# OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION

## 1902-1903

### GENERAL OFFICERS

|  |                             |
|--|-----------------------------|
| PRESIDENT—FRANK BILLINGS               | Chicago                     |
| FIRST VICE-PRESIDENT—J. A. WITHERSPOON | Nashville, Tenn.            |
| SECOND VICE-PRESIDENT—G. F. COMSTOCK   | Saratoga Springs, N. Y.     |
| THIRD VICE-PRESIDENT—C. R. HOLMES      | Cincinnati                  |
| FOURTH VICE-PRESIDENT—JAMES H. DUNN    | Minneapolis                 |
| SECRETARY—GEORGE H. SIMMONS            | 61 Market St., Chicago      |
| TREASURER—HENRY P. NEWMAN              | 100 Washington St., Chicago |

### BOARD OF TRUSTEES.

E. E. Montgomery, 1703 Walnut St., Philadelphia, 1905.  
H. L. E. Johnson, 1821 Jefferson Place, Washington, D. C., 1905.  
A. L. Wright, Carroll, Iowa, 1905.  
Miles F. Porter, Ft. Wayne, Ind., 1903.  
E. Fletcher Ingals, 36 Washington St., Chicago, 1903.  
W. L. Rodman, 1626 Spruce St., Philadelphia, 1903.  
John F. Fulton, St. Paul, Minn., 1904.  
T. J. Happel, Trenton, Tenn., 1904.  
W. W. Grant, Denver, Colo., 1904.

### JUDICIAL COUNCIL.

Term expires 1903: F. H. Wiggan, New York City; G. B. Gillespie, Covington, Tenn., and D. C. Peyton, Jeffersonville, Ind.  
Term expires 1904: T. C. Martin, Cleveland, Ohio; J. B. Roberts, Philadelphia, and Christopher Tompkins, Richmond, Va.  
Term expires 1905: Philip Marvel, Atlantic City, N. J.; George Cook, Concord, N. H., and N. S. Davis, Jr., Chicago.

### SECTION OFFICERS

**PRACTICE OF MEDICINE**—Chairman, W. S. Thayer, Baltimore; Secretary, James B. McElroy, Stoval, Miss. Executive Committee—George Dock, Ann Arbor, Mich.; J. M. Anders, Philadelphia; Frank A. Jones, Memphis, Tenn.

**OBSTETRICS AND DISEASES OF WOMEN**—Chairman, A. Palmer Dudley, New York City; Secretary, C. L. Bonifield, Cincinnati, Ohio. Executive Committee—W. E. B. Davis, Birmingham, Ala.; Henry P. Newman, Chicago; J. H. Carstens, Detroit, Mich.

**SURGERY AND ANATOMY**—Chairman, James E. Moore, Minneapolis; Secretary, John C. Munro, Boston. Executive Committee—H. O. Walker, Detroit; A. J. Ochsner, Chicago; DeForest Willard, Philadelphia.

**HYGIENE AND SANITARY SCIENCE**—Chairman, H. M. Fracken, Minneapolis, Minn.; Secretary, G. T. Swarts, Providence, R. I. Executive Committee—Arthur R. Reynolds, Chicago.

**OPHTHALMOLOGY**—Chairman, John E. Weeks, New York City; Secretary, Frank Todd, Minneapolis, Minn. Executive Committee—H. V. Würdemann, Milwaukee; J. A. Lippincott, Pittsburg, Pa.; Frank Ailport, Chicago.

**DISEASES OF CHILDREN**—Chairman, John C. Cook, Chicago; Secretary, Thos. S. Southworth, New York City. Executive Committee—Edwin Rosenthal, Philadelphia; Samuel W. Kelley, Cleveland; H. M. McClanahan, Omaha.

**STOMATOLOGY**—Chairman, M. L. Rhein, New York; Secretary, Eugene S. Talbot, Chicago. Executive Committee—M. H. Fletcher, Cincinnati; R. R. Andrews, Cambridge, Mass.; A. H. Peck, Chicago.

**NERVOUS AND MENTAL DISEASES**—Chairman, F. W. Langdon, Cincinnati; Secretary, F. Savary Pearce, Philadelphia, Pa. Executive Committee—Hugh T. Patrick, Chicago; H. A. Tomlinson, St. Peter, Minn.; Richard Dewey, Wauwatosa, Wis.

**CUTANEOUS MEDICINE AND SURGERY**—Chairman, John A. Fordyce, New York; Secretary, R. R. Campbell, Chicago. Executive Committee—L. Duncan Bulkley, New York; W. L. Baum, Chicago; Henry W. Stelwagon, Philadelphia.

**LARYNGOLOGY AND OTOTOLOGY**—Chairman, Geo. L. Richards, Fall River, Mass.; Secretary, J. F. Barnhill, Indianapolis, Ind. Executive Committee—C. R. Holmes, Cincinnati; J. N. Mackenzie, Baltimore; G. Hudson Makuen, Philadelphia.

**MATERIA MEDICA, PHARMACY AND THERAPEUTICS**—Chairman, Solomon Solis-Cohen, Philadelphia; Secretary, C. S. N. Hallberg, Chicago. Executive Committee—Leon L. Solomon, Louisville, Ky.; N. S. Davis, Jr., Chicago; George F. Butler, Alma, Mich.

**PHYSIOLOGY AND PATHOLOGY**—Chairman, Victor C. Vaughan, Ann Arbor, Mich.; Secretary, Joseph McFarland, Philadelphia. Executive Committee—W. S. Hall, Chicago; L. Hektoen, Chicago; Frank B. Wynn, Indianapolis.

### THE SPECIFIC AND NON-SPECIFIC LESIONS OF THE BRAIN RESULTING FROM SYPHILIS AND THEIR INFLUENCE UPON DIAGNOSIS, PROGNOSIS AND TREATMENT.

J. T. ESKRIDGE, M.D.

Allenist and Neurologist to the St. Luke's Hospital; Consulting  
Allenist and Neurologist to the Arapahoe County Hospital.  
DENVER, COLO.

That syphilis is due to a specific poison that is capable of causing the development of luetic lesions in non-infected persons is an indisputed fact. Whether this micro-organism belongs to the vegetable kingdom and may be classed among the bacteria, or whether it may be found in the lower forms of the animal kingdom and may be classed with the plasmodia, or whether it may occupy a place between the bacteria and plasmodia must be determined by the scientific investigator. We are as ignorant of the true nature of the virus as was Fernelius, when nearly 400 years ago he formulated the seven laws of syphilis. Syphilis of the brain can not be acquired except the virus enter the blood or other juices of the body through a denuded mucous or cutaneous surface. From the external manifestations of syphilis that we are able to observe, we are justified in reasoning concerning the internal manifestations of the disease, the early developments of which we can not see. While the virus of syphilis reaches the different portions of the body through the medium of the blood and the other fluids of the body, yet it attacks the most vulnerable solid tissues with which it comes in contact. This is shown by the development of a chancre at the point at which it finds entrance into the body. The most vulnerable tissues of the body seem to be the skin, the exposed mucous surfaces, especially of the mouth and throat, the iris and the membranes and blood vessels of the central nervous system, those of the brain standing first. It is a well-known clinical fact that when the skin, mouth, nose and iris escape, or to express it differently, in the absence of the secondaries, the brain and probably other viscera are much more likely to be affected. This would indicate that the virus expends its force on the tissues which it first attacks, or probably the true condition might be better expressed by saying that when the virus of syphilis once invades a tissue that that tissue then loses much of its resisting power to the poison and is most likely to be the seat of subsequent manifestations of specific lesions.

*Pathologic Conditions of the Intracranial Struc-*

*tures in Syphilis of the Brain.*—The lesions of the brain that may directly or indirectly result from syphilis may be divided into three classes: 1, the specific or luetic lesions, those that are caused by the poison of syphilis and by nothing else; 2, those lesions of the brain that may have a specific or non-specific origin, and 3, the non-specific lesions of the brain that occur as indirect results of the syphilitic virus.

It is of the utmost practical importance when possible to distinguish between the specific and non-specific lesions affecting the intracranial structures. Unless such a differential diagnosis is made we are at a loss as to treatment and totally at sea in regard to prognosis. Only the specific lesions, those that occur as direct results of the poison of syphilis, are especially remediable to antisyphilitic treatment: while the numerous injuries caused by the presence of specific lesions or the degenerations resulting from toxemic or other blood states which may possibly result from syphilis, are in no way specific in character, and yield no more readily to antisyphilitic treatment than do lesions resulting from causes wholly unassociated with syphilis.

**GUMMA.**—The typical specific lesions of the brain is the gumma. The first thing observed, especially in the meninges, is a small spot of inflammation. This soon leads to a knot of granulation tissue, which has been variously described as gray, grayish-red, semi-translucent or gelatinous. Early the new-formed tissue is extremely cellular and later becomes fibro-cellular. This mass of ill-formed granulation tissue, while it may continue to increase in size, soon begins to undergo caseation and fibroid degeneration in one or many spots. Evidence of congestion and inflammation mark the first stage and hyperplasia with degeneration, the second. The formation of the gumma is the direct result of inflammation, which undoubtedly has been lighted up by the poison of syphilis. It will be seen that it differs from the ordinary products of inflammation in being less highly organized and in having a greater tendency to degeneration. When the inflammation set up by the virus of syphilis is acute and violent, the inflammatory products at first vary but little from those of an ordinary or non-specific inflammation. It takes time for the gumma to assume its characteristic form. One of the greatest characteristics of specific intracranial inflammation, especially of the meninges, is its tendency to hyperplasia. The gumma varies in size from a line in diameter to several inches. It may be yellowish, reddish or of a grayish-white appearance, yet it usually has, when of recent formation, the feel and consistence of glue. No matter how large the gumma may become, nor how long it may have existed, it never becomes highly organized.

The degeneration may take place in one or two ways; either by caseation and fibroid degeneration, or by fibroid degeneration alone. Formation of masses of cicatricial tissues occurs as the result of fibroid degeneration. Gummatus deposits may be single, but they are frequently multiple. The brain substance adjacent to the gumma rarely ever remains intact, as the inflammation spreads to this. Gummata are most commonly found at the base of the brain, especially early, and the region of the interpeduncular space is a favorite site for the deposition of the products of specific inflammation. The sixth and branches of the third cranial nerve are often affected in the early stage. Gummata are often found on the cortex of the brain, invading the sulci, especially of the so-called motor region. They occasionally are found in the pons, rarely in the substance of the cerebrum and least frequently in the substance of the cerebellum. Gummatus inflammation of the membranes, both of the pia and dura is frequent, in fact, this is the most common form of intracranial specific inflammation. In inflammation of the membranes the tendency to hyperplasia is very great and the membranes, especially the pia, become so thick in the neighborhood of the optic chiasma as to present the appearance of a tumor. Inflammation of the dura is usually diffuse and the tissue form undergoes the fibroid change. It is thought to be most common in inherited syphilis. In the pia the inflammation is more commonly local, and the inflammatory products may undergo caseous, or fibroid change.<sup>1</sup> Finally, the walls of the arteries are frequently the seat of inflammation and of gummatus deposits. The sheaths of the cranial nerves undoubtedly may become specifically inflamed, and the nerves themselves damaged, either by extension of the inflammation, by pressure from gummata, or by constriction caused by the cicatricial tissue. That the nerve fibers and the brain substance have a greater immunity from the poison of syphilis primarily than do the meninges, the nerve sheaths and the blood vessel walls seems to be almost, if not, universally conceded, but that the brain and nerve substances are never the primary seat of specific inflammation, is doubtful, to say the least.

*Some of the Specific Lesions and the Non-specific Ones that Result from Syphilis.*—We must remember that while a specific poison is the cause of gummata, these by their presence, lessening intracranial space, by their irritating effects, encroaching upon and injuring adjacent structures, produce intracranial lesions that are in no way specific in character. Before considering the walls of the blood vessels, as affected by syphilis, let us try to study some of the effects of specific inflammation of the meninges. In an attempt at a differential diagnosis between the direct and indirect effects of syphilis, we must keep widely separated the idea of specificity and non-specificity.

I can not reiterate too often that this distinction is of the greatest practical importance in the prognosis and treatment of every case of intracranial syphilis. For the one class of lesions early in the disease, we have approximately specific medicaments; for the other there is no known medication of especial value. Recent gummata at the base of the brain exert pressure on the solid structures and interfere with their functions, the symptoms of the disturbed function depending upon the size of the deposits and their situation. The cranial nerves are compressed and irritated, and the membranes

are inflamed. If appropriate treatment is instituted in the early stage, before caseous and fibroid degeneration takes place, and before injuries to the structures compressed become well advanced, the whole morbid process may be removed and a cure, so far as the local brain trouble is concerned, is complete. But, unfortunately, vigorous treatment is not always instituted early; it does not take long for compression of nervous tissue to impair permanently, although it may not destroy, the function. Caseous and fibroid degeneration sets in early. Although the gummatus substance may be completely absorbed, the fibroid and caseous degeneration leads to the formation of cicatrices and bands of contracting cicatricial tissue. These are non-specific lesions, are not specially influenced by specific medications, and remain to compress and throttle the cranial nerves and keep up irritation to a greater or less extent in the membranes and in the brain substance. If, perchance, they remain latent, they mark the situation for subsequent specific inflammation on the application of any of the various exciting causes. It is to these non-specific lesions at the base of the brain, which have resulted from specific inflammation, that many cases of impairment of vision, blindness, ocular paralysis, and chronic basilar headaches are due. These, of course, fail to respond to antisypilitic agents. Many cases of optic nerve atrophy and of permanent paralysis of one or more ocular muscles may be thus explained, both in children and adults; for, it must be remembered that gummata occur as the result of hereditary syphilis as well as from that which has been acquired.

Gummata on the convex surface of the brain are most likely to occur in and around the motor convolutions. The effects, both from the specific and non-specific lesions, on these structures, the cortex and membranes, are the same as when the inflammation takes place at the base, but the symptoms are different. The same remarks apply to the effects of syphilitic growths within the brain substance. It may be added that intracerebral syphilitic growths are rare and probably arise from some portion of the pia. The characteristic form of specific intracranial inflammation is syphilitic meningitis. It is doubtful whether this form of meningitis, in the true sense of the word, is ever acute. In other words, an apparently acute attack of syphilitic meningitis is secondary to a pre-existing local and chronic specific inflammation of the membranes. If this is true, and I have seen no reason to doubt it, a syphilitic meningitis is always subacute or chronic; although acute outbreaks are not uncommon. Great thickening of the cerebral membranes sometimes takes place from specific inflammation. These thickened areas or patches in the membranes denote chronicity, and in consequence, while they are due to syphilitic inflammation, they are degenerative in character, composed of bands of firm fibrous tissue, the results of caseous and fibroid degeneration, and are not purely syphilitic in character. At the base of the brain these bands of fibrous degeneration are most commonly found in the neighborhood of the optic chiasma and in the interpeduncular space. Syphilitic meningitis, involving the convexity of the brain, is not infrequent, especially affecting the pia over the anterior and parietal lobes in the vicinity of the longitudinal fissure. According to my experience, when the dura is inflamed in this region the pia rarely, altogether escapes; especially have I observed this when the cranial bones of the vault have been inflamed. The pia,

1. Gowers: *Littsomian Lectures on Syphilis and the Nervous System*, 1892.

on the other hand, may be inflamed and the dura remain free. In syphilitic inflammation of the pia the cortex is involved in the inflammatory and degenerative processes. We have a meningo-encephalitis which is partly due to meningitis and partly to degeneration of the arteries of the cortex. Here, again, while the specific inflammation has been mild and the specific exudate comparatively slight, the non-specific lesions are extensive, very destructive, will not respond to antisiphilic medication, and hence are permanent in their effects.

There is one other change in the membranes to which I wish to direct attention. This is chronic thickening of the dura in the posterior cerebral fossa. It is commonly found in childhood as the result of inherited syphilis. I have only seen one case of this affection. It occurred in a child about 3 years of age, the offspring of infected parents. It had been sick for several weeks before it was admitted into the Arapahoe County Hospital. The head was extremely retracted; the body became greatly emaciated; but the patient lived, after it came under my care, one year. At the autopsy the dura of the posterior fossa, especially that portion surrounding the pons and medulla, was thickened, and the seat of old fibrous deposits. Some of these cases are said to have recovered. It is just possible that some cases of reported recovery from tubercular meningitis may have been cases of syphilitic meningitis.

*Blood Vessels in Syphilis of the Brain.*—We now pass on to syphilitic inflammation and degeneration of the blood vessels of the brain. Syphilitic endarteritis and peri-arteritis have been observed and minutely described by nearly every writer on syphilis of the brain, but so little has been said about syphilis of the veins that I shall quote from a case cited by Mickle.<sup>2</sup>

CASE 1.—Female, aged 45, died in an epileptiform attack due to hemorrhage at the brain base, from rupture of a syphilitic vein. There were clear signs of early general paralysis, and tabetiform ones due to diffuse embryonic meningo-myelitis. Syphilitic lesions affected the large vessels of the brain and cord. A diffuse vascular lesion affected the cerebral gray cortex, and in a less degree the subjacent white substance.

The large arteries of the brain present slight patches of ordinary secondary obliterative endarteritis; but the chief lesion is an infiltration of the embryonic cells in the adventitia, forming an intense peri-arteritis, diffuse, but in places nodular—the first stage of a gummatous process. In the veins the muscular connective tunic is lesed; in them the infiltration, although usually diffuse, takes here and there a nodular character, even more clearly, and so as to form miliary gummata when "caseification" sets in. The venous lesion exceeds the arterial at the brain base, where it has led to hemorrhage, and at the surface of the cord, and is largely independent of the meningeal and arterial lesion. The endovena does not show any proliferation; when it is affected it is so through invasion by the gummatous process. Hence, the ulterior tendency of the luetic arterial lesion is to narrowing, obliteration, and their results; in the veins, to hemorrhage.

Personally, I have not met with a case of venous hemorrhage due to syphilitic degeneration of the vessel.

ARTERIES: Gowers, in speaking of arterial degeneration, states that "except in the arteries of the brain and in the aorta, syphilitic disease is scarcely known."<sup>3</sup> In this he is mistaken, as syphilitic degeneration of the spinal arteries is not uncommon.

The walls of the medium, and sometimes of the larger, arteries of the brain are affected by a syphilitic inflammation and gummatous deposit, involving especially the

inner coats—the intima and endothelial lining—of the vessels. This process is known as endarteritis, and on account of the tendency to obliterate the caliber of the affected vessel is sometimes spoken of as arteritis obliterans. In some cases, before the caliber of the vessel is closed, a small branch given off by the vessel is blocked and the blood supply to a very small area of the brain may be cut off. If a small artery, especially of the cortex, is thus closed, the collateral circulation may be sufficient to prevent necrotic softening, but it may not be sufficient to maintain the normal condition of the part, and this may explain the spots of induration found in the cortex of the brain, especially in syphilitic children. When the caliber of a medium or large vessel is occluded, necrotic softening in the area of distribution of the affected artery must take place, as the collateral circulation of the brain is so meagre that Nature is unable to provide against such violence. It is important to remember that the final closure of the vessel is due not to gummatous deposits, but to a blood clot formed at the narrowed portion of the vessel. Thus, while the greater portion of the vessel's caliber has been occluded by a specific lesion, the closure is finally completed by non-specific material that is not specially influenced by anti-syphilitic treatment. We have, then, in all cases of syphilitic occlusion of a vessel two non-specific lesions; one, the blood clot that completes the occlusion of the vessel, and the other the necrotic softening in the area of the brain to which the occluded vessel is distributed. These facts should be borne in mind in the prognosis and treatment of all cases of syphilitic thrombosis.

Gowers states: "A second effect is the production of aneurysm of the larger arteries—those that are the special seats of the disease."<sup>3</sup> The explanation given for the formation of aneurysm is inflammation and degeneration of the vessel wall by which extensible fibroid tissue is substituted for the elastic elements.

Mills, in his volume on "Disease of the Brain and the Cranial Nerves," says peri-arteritis attacks the smaller arteries and may give rise to miliary aneurysm and hemorrhage. In a case recently under my observation peri-arteritis involving the nutrient vessels of the pons resulted in local softening and death. Peri-arteritis of the nutrient vessels of the brain is not rare, but hemorrhage into the brain substance from specific inflammation of the vessel is infrequent.

I shall not tarry to discuss cases of supposed specific inflammation of the substance of the brain. Charcot and Gombault reported a case of chronic disseminated inflammation, with foci in the cerebrum, pons and optic nerves, and the tissue in many of the foci had undergone caseation. Barlow has observed foci of sclerosis in the cortex of the brain, without arterial degeneration in syphilitic children.

Gowers observes: "The spinal nerves seem to escape the influence of syphilis, and the cranial nerves suffer chiefly at the base of the brain, where several are involved in a focus of inflammation. To this some of the nerves to the eyeball seem to offer an exception; they may suffer alone. The facial nerve presents a remarkable freedom. The nerves that arise from the side of the medulla are often involved, especially the hypoglossal and spinal accessory causing palsy of the tongue, palate and vocal cord on one side. These palsies are seldom due to any other cause, so that their occurrence should suggest syphilis at once to your mind."<sup>4</sup>

2. W. Julius Mickle: On Syphilis of the Nervous System, Brain, 1895, part I, pp. 115, 116.

3. Gowers: Syphilis and the Nervous System, p. 19.

4. Gowers: Littsoman Lectures, Syphilis and the Nervous System, 1892, p. 43.

Many of the nerve degenerations, both nuclear and system, are caused by the poison of syphilis. Some of these are evidently due to a primary degeneration of the nerve elements, and others may result from inflammation of the interstitial tissue. Whatever may be the method by which the degeneration is brought about when it has once occurred, antisyphilitic treatment can do no good.

It should be borne in mind that multiple lesions in syphilis of the brain are the rule. It is not uncommon to find most of the larger arteries at the base of the brain affected with gummatous deposits. In cases of syphilitic tumors of the brain it is the exception to find the blood vessels healthy. On the other hand, the walls of the arteries are the seat of numerous gummatous deposits, while the other structures of the brain are free from the appearance of syphilitic disease. We may conclude from this that the blood vessel walls are the most vulnerable intracranial tissue to the virus of syphilis.

### TREATMENT OF NEURASTHENIA.\*

J. G. BILLER, M.D.

CHEROKEE, TOWA.

I suppose we all recognize the fact that there never can be any ready-made, hand-me-down treatment for neurasthenia. When we consider neurasthenia from an etiological standpoint, and then attempt from this consideration to evolve a rational treatment that will not only cure the patient but at the same time make him or her comfortable enough to live until the cure is effected, we certainly have ample food to satisfy our appetite for conundrums.

It is all very well to say that the principal causes of neurasthenia are toxin, malnutrition, fatigue, or emotions, and that the treatment depends upon the cause. This of course is so, but it is just as true that we may have a patient that is long on causes and has a neurasthenia that is caused by all of these conditions combined, and this is not all, as the nervous system governs and controls all the organs of the body, and as these organs take advantage of the weakness and irritability of their masters to act in all sorts of irregular and uncomfortable ways, it is no easy task to tell whether their action depends upon the neurasthenia, or the neurasthenia depends upon them. When we consider this jumbled up mess of cause and effect and effect and cause, it is not surprising that we sit down in despair and wonder what to do first. I find it best to first carefully examine the patient, being sure to ascertain the condition of each and every organ as well as possible; also inquire into the habits of the patient. This examination may or may not give us much information, but if it does not, it gives the patient confidence in us, or at least helps to do so, and this I consider a very important part of the treatment.

#### CONFIDENCE OF THE PHYSICIAN.

All of us, of any considerable experience, have treated many cases of neurasthenia successfully and probably as many more without success, and as we carefully review our work we are unable to see why one patient should have recovered, and another failed to do so. It is often humiliating to see a patient whom we have failed to benefit, gradually and continuously improve, under possibly the same treatment, in the hands of another physician. We may break the force of the fall by de-

claring that there was nothing the matter, or they would have improved just the same in our hands. I do not believe that such is the case. The different results are due simply to the fact that we did not have the confidence of the patient, and our successor did. I have become so certain that confidence in my ability to do the very best that can be done for them is such a necessary factor in the bringing about of a cure in these cases, that I rarely take charge of a case of neurasthenia where there seems to be a lack of faith in me; it is true that it sometimes takes more tact and management than I possess, to successfully pass them over, and I am forced to treat them, but I do so with my mind fully prepared for their departure.

Do not think that I believe the only thing necessary to cure these people is faith; for, such is not the case; but a neurasthenic nervous system is lame, and in such a condition that it must have someone as a nervous crutch to help it along from time to time, until once more strong enough to go alone, and as a rule the attending physician must be the support. This is plainly demonstrated by the fact that, after seeing the physician and having a chance to relate their various bad feelings, and being reassured that these are nothing to be alarmed at, etc., for considerable time the patient gets along nicely. But after so long a time we have to go over the same ground again; they require the same reassuring and once more are strengthened and feel better for a longer or shorter period varying according to the condition of their nervous system or the external conditions brought to bear upon it. These things often seem childish to us, who are strong and well, but they are important to the patient, and it is for this reason that our visits and consultations with these people should not be hurried nor too far apart.

#### DIET.

Proper feeding is an important, and often neglected part of the treatment. I have seen delicate women who were what we might call natural neurasthenics—that unfortunate class who are launched into life with a nervous system so frail that it can scarcely supply sufficient nerve force to meet the ordinary demands of living—I have seen these delicate women systematically starved for years, while they underwent all kinds of scientific treatment: drugs galore, electricity, massage, and even starvation by rule at well-known sanitariums. After having endured these things, without benefit, while in the hands of men of reputation and skill, they naturally wandered outside of the regular routine and took in the novelties, as osteopathy, etc. After all this I have seen them improve as if by magic when put on a liberal diet of common-sense food, accompanied by such medication as assists nature in digesting and assimilating the food taken. It is not feeding these people properly to place them on a diet composed of these high-priced concentrated foods, that one teaspoonful equals in nourishing power the flesh of two oxen and ten sacks of flour; their stomachs will not stand it, more padding is required. Neither is chopped feed, no matter how well roasted, nor how well and attractively it may be packed, nor how skilfully advertised, nor how highly endorsed by medical authority. We are too apt to think that, because the patient complains of unpleasant and disagreeable sensations in the stomach after having taken food, that the stomach is being worked beyond its capacity, and that the amount of food must be diminished. It has often been a surprise to me to see how one of these starved and pampered

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Hugh T. Patrick and H. A. Tomlinson.

stomachs will behave, when its complaints are treated with silent contempt, and it is regularly and frequently filled with plain nourishing food, such as oatmeal and cream, stale bread and butter, milk, potatoes and beef-steak, soft cooked eggs, etc.

All cases of neurasthenia do not require to be put on a stuffing diet; but nearly all want some considerable attention paid to it. While many cases are suffering from underfeeding or rather no feeding, many others are suffering from overfeeding, or wrong feeding. It is no unusual thing to find men who are exhausted by long and hard mental work, attempting to get rid of their depressed feeling by taking large and heavy meals, which simply aggravate their trouble. I have recently seen one of these men whose occupation required the most exacting and continual mental effort for eight hours during the night, who habitually took a breakfast of baked beans and pork, or a large beef-steak and fried potatoes and finished with some kind of pie, usually mince; then go home and to bed to awake a few hours later, with a palpitating heart and all sorts of paresthesia, which frightened him terribly. This particular man had been under treatment for many months for his neurasthenia, but no inquiry had ever been made as to his diet, although he had consulted several physicians. The rapidity with which he improved when put on a more rational diet, demonstrated the importance of the physician knowing how much and what kind of food his patients are eating, if he expects to treat them successfully.

#### FRESH AIR.

Another important thing in the treatment of these cases is plenty of fresh air, and it is strange to say that although there is no end of this great necessity which is all about us, yet our patients suffer more for the want of it than we fully realize. This is well shown by the fact that we have all learned by experience to expect that these delicate cases, which I have referred to as natural neurasthenics, will have a sick spell along towards spring of each year. I have thought these attacks could often, and possibly always, be avoided if these unfortunate people could only have an abundance of fresh air, obtained out of doors during the winter. We hardly realize how long and continuous is the confinement of these frail women, in the close rooms of one of our atrocious modern homes, where often every device that money can purchase and mechanical ingenuity contrive is brought into play to shut out fresh air, and replace it with overheated air that probably has been in the house for days and weeks. It seems impossible to contrive ways and means that will make it possible to get them out each day for a longer or shorter time. They are too feeble to stand the physical exertion necessary to keep them warm, and the weather is too cold for them to get out and sit around without taking exercise; still each year I become a little more determined, and insist a little stronger on their not staying in the house all the time.

#### REST.

Rest is also of great importance in neurasthenia, both mental and physical rest, and in no way is this obtained so well as in sleep, which is nearly always poor in this class of people. Good feeding and good air does much to help them sleep, but occasionally and sometimes frequently, for a time, these people must have a soporific. I have found sulfonal, in small doses, usually the best for this, but it should only be dispensed by the physician himself, and if possible the patient should not know

what he is taking. For, often the rest by night is desired, only to enable the patient to carry on some exhausting labor during the day, and if he has the drug in his own hands he will get to depending upon it and may do himself much harm, not only by acquiring the habit of using a hypnotic, but also by enabling him to benumb nature and wear himself out without realizing what he is doing; I think the physician should not become a party to any such thing. If people want to ruin themselves mentally and physically we may not be able to prevent it, but we can refrain from helping them. It is sometimes impossible to have people take the required amount of rest at home, where everything continually reminds them of the work they are attempting to forget and abstain from; for this reason it may be wise to advise a change, but this should be done carefully; too frequently the change taken is only a change from one form of labor to another, and the patient comes back to you in a worse condition than when he went away. If he is sent from home he should be sent where he will be able to rest, not where he will have to rush here and there to visit this person and that historical place; these things will divert the mind, but do not rest the tired brain or body, and the latter is the necessary thing, and though some diversion may be required to make the rest bearable, we must keep the fact in mind that this is but of secondary importance.

#### MEDICINAL TREATMENT.

Besides the proper feeding, fresh air, and rest, I believe there is a large field for the judicious use of medicine, but to attempt to cure one of these cases, by using the so-called tonics, will be disappointing to both patient and physician. The remedies that I have found of benefit are those that assist in digestion and increase the activity of the liver; the latter organ is too much neglected.

I have been surprised at the benefit that has been derived from a quarter grain of calomel every second night for a week or so; it often produces great pain in the bowels and nausea, but after this, the stomach acts better, the bowels are not distended with gas, and there is a general feeling of well-being in the patient. Besides these, it is necessary to relieve the many distressing sensations which are annoying the patient. I will not attempt to enumerate these, for they are all so well known to us that it would be a waste of time to do so. I will add that I have found, as a rule, that the older and more simple remedies are usually the producers of the best results in relieving these things and do not leave as bad a condition as many of the newer and higher-priced ones.

In closing this paper, I wish to say that I am well aware that the ideas here advanced are not new. I have found them of importance in my own work, and so generally ignored in the practice of many with whom I come in contact, that I feel it my duty to keep continually calling the attention of the profession to rational management of this affection, instead of being led hither and thither by those will-o'-the-wisps, so persistently dangled before us by interested parties.

#### DISCUSSION.

DR. J. H. MCBRIDE, Los Angeles, Cal.—It is a significant fact that the man who first gave us a rational treatment for a certain class of nervous disorders, Dr. Weir Mitchell, was the author of those beautiful essays called "Characteristics," which show how thoroughly he understood human nature and what we may call the psychology of daily life. The physician who does not grasp the mentality of his neurasthenic patients

may cure some of them, but he will cure them by accident, for the mental condition is the first thing to understand. A very important consideration in the management of the neurasthenic is the outdoor life and exercise. In Southern California where we have 340 sunny days in the year we have an ideal climate for such people. The neurasthenic should be told by the physician how far to walk and how often and when. The details should not be left to others. A veranda or pavement is not a good place for an invalid to walk. Walking on a pavement is much like running a sewing machine. The soft, yielding ground is the better place. The patients should be forbidden to climb hills until they have grown strong. A patient of mine lately overdid this and had to return to bed. I can hardly endorse the Doctor's prescription of oatmeal and cream. Oatmeal is a pasty mass and the mixture is not easily disposed of by the delicate stomach. The indigestion and prostration of many of these people are not infrequently aggravated by their living on liquid diet. I recently began treating a lady who for many months had lived almost exclusively on liquid diet. I gave her a beefsteak at noon, and she said she had less trouble with it than with any meal for a great while.

DR. JOHN PUNTON, Kansas City—The treatment of neurasthenia is very important from the standpoint of the general practitioner, and I think the question of expense ought to be considered in any paper on the subject. Many patients who would attempt to follow the plan of treatment outlined in Dr. Biller's paper would require a considerably larger bank account than they could command. It is necessary to make some provision for the poorer neurasthenics, as well as for those who subsequently become insane, because I believe there is a close relationship between neurasthenia and insanity. In fact, it has been claimed that the more serious forms of neurasthenia are really forms of insanity. It is very difficult to draw a line of demarcation between an aggravated neurosis and mild melancholia. I think every state should make some provision for neurasthenics belonging to the poorer class.

DR. C. EUGENE RIGGS, St. Paul—In the treatment of neurasthenia the best tonic is good food. The iron preparations are of value in their proper place, but better than these and more essential is nourishing and easily digestible food. Nor should we underrate the importance of the confidence of the patient in the physician, although I do not regard this as absolutely essential, because if we have the case well in hand, and understand this subject as professional men should, we can so handle our patients that faith will come in consequence of the success of our treatment. As to whether we should advise a neurasthenic to travel or not, that is a two-edged sword. It may benefit him or it may harm him. I remember the case of a man who had apparently recovered from his neurasthenia. He took a continental tour, and while away from home developed acute melancholia and finally committed suicide. I know of other cases where travel resulted disastrously, and I feel that in any case it should be advised with much caution.

DR. HAROLD N. MOYER, Chicago—I think that the problem we have to deal with in the treatment of neurasthenia varies in different parts of the country and according to a man's clientele. We have to adapt our treatment along the general lines laid down by the essayist, but it must be modified according to the indications of the individual case. I would emphasize the suggestion that a large dose of "Doctor" should be given with any form of treatment. In two cases of neurasthenia under observation during the last winter one was cured by complete rest, and in the other the patient recovered under a modified rest cure, a modification of the treatment in both of these cases consisting of keeping the patient in the open air for several hours each day, even when the weather was very cold. On the first day one remained in the open air for four hours, on the second day for six hours and on the third day for eight hours. The improvement in this case was immediate and remarkable. The nutrition was influenced beyond anything I had ever seen in connection with the rest cure. In another case, where I was not able to have the patient taken out of doors and could only remove the windows of her apartment for a part of the day, the result of the treatment was

not quite so marked, but still it was satisfactory. I simply mention these instances to show the value of out-of-door treatment in a climate like that of Chicago in mid-winter, which I consider far ahead of that of Florida or Los Angeles or any of the so-called "soft" climates.

DR. F. SAVARY PEARCE, Philadelphia—In regard to the best form of exercise for neurasthenics I would recommend horseback riding, for the twofold reason that the patient does not exert himself too much and gets plenty of fresh air, and furthermore, because a man can not think about himself while riding horseback. I have seen excellent results follow this form of exercise. I certainly disagree with the suggestion made by Dr. Punton regarding state aid in the care of neurasthenics. For the same reason, I would dissent from the possibility of anything in the line of institutional treatment in these cases, because we wish to remove these patients from an environment which would tend to increase their introspection.

THE CHAIRMAN, DR. H. A. TOMLINSON, St. Peter, Minn.—The question of proper feeding in its relation to the treatment of nervous disease is a very important one, and its consideration leads one to appreciate the force of the dictum of Sidney Smith: "The Lord made the food, but the Devil made the cooks." The physician himself is not sufficiently acquainted with the chemistry of food, or its proper preparation, to say how it should be prepared and know when it is properly done. Food is more often spoiled in cooking than improved and wrong preparation will make any food indigestible. People in general have queer tastes and appetites, and this is especially true with regard to neurasthenics. Another important element in the treatment of these cases is elimination. While we are coming to appreciate the important part played by auto-intoxication, we are not as fully alive to the fact that the results which follow from that intoxication are made possible by faulty elimination.

In the care of the neurasthenic at his own home we meet with the difficulty of dealing with a certain class of people who have neither the domestic facilities to properly care for the patient, nor the mental training necessary to appreciate the importance of the various phases of treatment; and it therefore becomes essential, as Dr. Moyer has already pointed out, that a large element of "Doctor" should enter into the treatment of these cases, and that the attending physician should carefully train a member of the family to carry out his instructions. The foolish sympathy and constant solicitude on the part of the various members of the family, as well as the lack of will power to control the patient, often renders futile the efforts of the physician in the treatment of these cases. These may appear to be trivial points, but I believe that many failures are due to our not appreciating them.

DR. J. G. BILLER, in reply—In regard to the question of diet, I only referred to it in a general way. I agree with the gentleman who spoke of the value of beefsteak as an article of diet in these cases. I look upon large, well-cooked steaks as a very important part of the diet. The majority of our cases of neurasthenia occur among poor people, and it is a conundrum to know what to do with them. The burden falls on the physician, who frequently lays down his rules of treatment only to find at his next visit that they have been amended at the suggestion of some of the neighbors. As regards travel in these cases, it is a thing which should be prescribed with care. I recently had an illustration of its harmful influence in the case of a neurasthenic woman who was in very good circumstances financially. She was an ambitious and intelligent woman, who did a great deal of intellectual work, reading papers before societies, etc., and in the course of time she broke down and developed symptoms of neurasthenia. Frequently, at night, she would have attacks when she thought she was going to die. I did what I could for her, and fortunately, about that time, she developed typhoid fever; this gave her a good rest and when she recovered from the typhoid her neurasthenic symptoms had also disappeared. Subsequently, she again took up her literary work and traveled extensively, attempting to visit as many historical points as possible, and as a result of this she again developed symptoms of neurasthenia, for which she is now, I believe, under the care of an osteopath.

## THE NERVOUS RELATION IN DISEASES OF THE NUTRITIVE SYSTEM.\*

HENRY S. DRAYTON, A.M., M.D.

NEW YORK CITY.

We may postulate as a general statement that those who have given attention to the causal relations of American dyspepsia are agreed that our social habits, our methods of business, our irregularities and excesses of diet, and our nerve excitability, lie at the bottom of most of our stomach troubles. As a single causal factor it would be agreed that the wear and tear incident upon our excessive nerve activities as a people are much too severe for the maintenance of gastric integrity. The strain almost continuously put upon the central nervous system reacts disastrously at the sympathetic foci of food conversion. Nevertheless, it is not the amount of work actually done, not the muscular exertion nor the nerve labor in itself that are responsible for the diseases of the stomach and intestine; but it is the manner in which the work is done, the excitement and irritation to which we subject ourselves.

### AIDS TO DIGESTION.

With this very brief reference to the etiologic factors of our national dyscrasia, let me pass to a brief consideration of the trend of opinion with a large class of pathologists concerning the treatment of gastric disorders, which may be introduced in the following parliamentary style: Whereas digestive enfeeblement is due to incapacity of the organism for the proper conversion and assimilation of food substances, to-wit—the stomach failing to secrete its normal juices, the liver being incompetent to produce sufficient bile, the pancreas too feeble to supply its quota of emulsifying fluid to the duodenum, the spleen overcrowded for the exercise of its function, it is necessary to supply in some convenient form, as mechanically or chemically prepared, compositions and extracts organic or inorganic, which shall aid to the effective operation of the digestive apparatus, and thus supplement the needs of human nature for tissue nutrition.

How respondent to this is the manifestation of interest on the part of druggist and chemist, who would supply the physician with the organic derivatives, the peptonates and the diastases, and other kindred incitants of stomach function! The professional consensus is thus complemented by the commercial or business interest, and it would appear that such a combination should meet the popular demand in so happy a fashion as to furnish relief to all digestional woes. But is this the case? Really far from it. Indeed, so far from it that there are some physiologists who assert that we are almost as much in the dark with regard to understanding the vital procedure of digestion as were our grandfathers; and however skilfully we may treat stomach and intestine our peptonates and maltates and enzymes will have but a limited range of usefulness. Whether the trouble of our patient be salivary, peptonic, amylaceous, hepatic or what not, the products of the laboratory fail to produce the intended effect.

One has said of amylaceous dyspepsia: "It has long been a problem of the profession, a *bele noire* of disease which we could not reach. If we used alkalies we rendered the saliva too alkaline; if we prescribed acids we neutralized the naturally existing alkalies, so necessary in that fluid. . . . It does not always happen that

digestion occurs in the test tube exactly as it is thought to occur in the human stomach; there are, however, many things to be gathered in the study of digestive ferments from theories in the lecture room and tubes in the laboratory."

The experiments of Beaumont with Alexis St. Martin, and the later experiments with tubes that are introduced into the stomach of the living subject furnish many lessons regarding what nature does with this or that substance.

### NATURE'S RESOURCES.

In our zeal to provide aids and substitutes for digestion the proper value and capacity of natural function seems to be overlooked. We limit the power and quality of the nervous apparatus having relation to gastric function and need to be reminded that nature has endowed it with a very broad field of adaptation as concerns foodstuffs; it will appropriate to the purpose of nutrition substances widely different in composition. From the whale blubber of the Eskimo to the viscid clay of the Ottomacs its capability of conversion indicates a protean diversity, so that the term "omnivorous" of the naturalist is not far-fetched in its application to the human alimentary function.

Of the races and tribes of the world scarcely two feed alike, yet all find in the products of their habitat sufficient material, be it animal or vegetable, of the land, sea or air, to satisfy the cravings of appetite. The peasantry and laboring masses of Europe content themselves for the most part with cereals—oatmeal, bread, potatoes, rice, barley and maize—with the addition of vegetables, milk, butter, cheese, oil, etc., according to custom, or necessity. The well-to-do Englishman demands his mutton chop or rib of beef as essential to his vigor, while the Scotchman maintains a higher degree of general robustness on his porridge and milk. The hardy "bashi-bazouk," after a day's hard fighting amid the mountains of the Caucasus, regales himself with black bread and onions, while that Yankee of the far East, the nimble Jap, is content with a handful of rice to begin and end a day of severest toil.

It is not long since physiologists found it necessary to modify views on tissue nutrition that had been regarded for a long time as standard. The teaching that foods were divided into muscle-building proteids and the oxidizing carbonaceous foods is now disproved, and we are more certain that nitrogenous or proteid tissues are not alone the result of proteid compounds and that fat accumulation in the body is not due altogether to consumption of fats and carbohydrates. It is also known to the experimental observer that hard work has little if any effect in the consumption of nitrogenous tissues beyond the degree of such consumption when the person is at rest; while muscular activity is attended with loss of carbonaceous matter. The disposition of mankind at large to use a large proportion of the carbonaceous compounds in their diet is thus seen to be but a natural expression of physical need.

Assuming, however, that such a proposition as that proposed by Professor Voit to be correct, namely, that in the foodstuffs required to maintain equality between bodily income and expenditure, there should be five times as much of the fats and carbohydrates as of the proteids, man has but to eat sufficient food to obtain these proportions at least. It must be noted that the proportion above stated is the result of studying the relation of diet to physical exertion. People generally respect the demands of the appetite and pay little attention to eco-

\* Read at the Fifty-second Annual Meeting of the American Medical Association in the Section on Physiology and Dietetics, and approved for publication by the Executive Committee.

nomic principles in their choice of a dietary. To be sure, more regard is paid by modern society to the hygiene of diet than formerly—yet is dyspepsia less common among us? I would not go the length of Fothergill in decrying the use of artificial digestives, but I feel justified in maintaining with Manges that the usefulness of the various ferments, etc., in gastric disorders is a limited one. Further, I would call attention to the fact that this opinion finds a recognition in most of the later treatises on the physiology of digestion or diseases of the stomach.

#### RELATION OF NERVE FATIGUE.

While the chemist may obtain results in tube or beaker that appear very definite in character as regards the potency of a certain enzyme, it must be appreciated that the biochemistry of the human body is quite another thing, that the processes of life have certain peculiar properties in their operation that are entirely wanting in the action of the pepsin or the ferment that is mechanically placed in the laboratory tube. Certain reactions may be positive enough in the test tube, but in the stomach those reactions may never occur, or be so modified by the conditions within the stomach as to be quite negative in result. Hence it is that the physician is so often disappointed in the sequelæ of a treatment of which he had formed a most sanguine view. The nervous relation of alimentation, the vital sources of gastric change, had not been sufficiently considered; the power of the stomach secretions to decompose and change, and counteract the remedies exhibited had not been adequately estimated.

Further still, it is to be considered that nature has reserves that may be put into the gastric field and do excellent work in cases considered desperate. Even in the absence of pepsin or rennet in the secretions of the stomach membrane, there are the various enzymes and salts of the pancreatic, hepatic and intestinal secretions that are capable of doing the work of conversion. Kellogg<sup>1</sup> reports as one result of a careful examination of the stomach contents of nearly 4000 patients having chronic disorders of that organ, that a deficient amount of ferments was discovered in but 1 per cent. of them all. The fact that these ferments exist in the body and that their deficiency may be the cause of intestinal disorders is the chief warrant for the administration of the artificial substitutes. Probably it is no libel to say that a large number of us employ them as a convenient form of placebo in cases where the patient's condition suggests little if any active medication. This is done, too, with the impression that if the ferment does no good it will do no harm—an illogical notion, and really pernicious in effect. These artificial substitutes for the natural products of a living organism may do harm. This has been urged by Brunton, Laabe, Grote and others, and in the circulars and "essays" of the manufacturers we may daily read of the inadequacy and inequality of this or that peptonate marketed by some competitor.

But of the contentions and rivalries and theories of chemists and dietiticians, the great body of people care not a jot. To satisfy appetite is the main purpose of eating with them, and that which is simple, "hearty" and coarse is preferred to the elaborate dishes of the epicure. Note the buxom men and women, the plump, red-cheeked children of the laboring classes, especially those from other lands; their intelligence rises not into the realm of contemplating their food through the glasses of the hygienist. The sturdy mechanic sits down to a

table that is laden with a stew, or a roast, or a soup, flanked with a side dish of potatoes or cabbage, a liberal chunk of bread and a cup of coffee or tea, eats to contentment, and afterward goes to his bench or recreation without a thought of his stomach. Your cultivated merchant or professional man, fastidious and finical in his eating, is troubled with a rebellious stomach; his nerves are over-sensitive. The elaborate variety he deems of so much importance to good digestion and thorough nutrition does not save him from pyrosis and constipation.

The hospitals and sanitariums for chronic disease are attended in the great majority by dyspeptics. These furnish us a history of nerve function irritated and worn by irregularities and negligence, and if they find relief and healing at their chosen retreat, it is because of its simple food and restful régime.

#### CONCLUSIONS AND COROLLARIES.

Looking at the subject of nutritive failure from the point of view of nerve fatigue it is not so remarkable that the broken-down stomach will exhibit as a rule a ready capability for the recovery of its functions when given the needed opportunity by the abandonment of the unnatural course of life that has impaired it. If in ordinary affections of the alimentary system the nerves play an important part, how much more important is their relation to wasting diseases, such as tuberculosis, carcinoma, ulcers, diabetes, chronic nephritis, etc., diseases that force the food question into most conspicuous notice! I believe myself warranted in saying that here especially the office of the nerve centers is accentuated and must be taken into careful account with regard to any treatment. In kidney maladies prohibition of starchy foods, oils and fats may appear to modify symptoms favorably, yet the continued decline of the patient in strength indicates that the good supply of proteids we may put into his stomach is not properly assimilated. The "restricted diet" is not what is indicated, and we return to the "all around" feeding; there follows a gain in weight and the patient feels better generally.

But does the absence of carbohydrates in the so-called "diabetic dietary" prevent the production of sugar? No. The blood contains sugar, normally. The tissues contain a good proportion of the carbohydrates, and thus in themselves furnish the material for the organic production of glucose. These are facts to be appreciated in our management of kidney derangements. A healthy man could not live on a purely nitrogenous diet, as Landois says, and as experience teaches; so that in a disease of such rapid metabolism as diabetes it is apparent that the food should be as much as possibly of the mixed variety.

That the nervous apparatus of the stomach must play a large part in the diabetic expression seems to me to be clearly made out by the fact obtained in the exhibition of codein, to which high value is very properly given as a remedy in the therapy of diabetes. Several years ago while on my way to Northern Vermont to attend a consultation I fell in with an elderly clergyman, who, learning somehow of my profession, gave me a history of his experience as a diabetic. He had been a missionary in Africa for many years, and finally, on account of the malady, was compelled to withdraw from active service. On his route homeward he fell in with an eminent English physician, who put him on "codeia" with such excellent effect that he found himself after a little time in a comparatively comfortable state, and he assured me that this was the situation at the time of our meeting.

A little thought upon a case such as this would make

1. *Modern Medicine*, March, 1896, p. 57.

sufficiently clear the relation of the nervous system to the gastric and renal lesions involved in functional innutrition and convince us of the existence of a neuro-alimentary dyscrasia as the basic element in the malady. The pathologic showings, such as we have, of the importance of the duodenum as a functional center for those metabolic changes by which the saccharine matter is derived, intimate the relation of the "second stomach" to the etiologic factors in diabetes. Dr. J. M. Allen, in a paper before the Association, in 1899, reviewed the symptoms, and pathologic evidences in twenty-six cases, and arrived at the conclusion that it is the duodenum in which chiefly occur the lesions that are causative of the dreaded malady. Taking into consideration the origin and distribution of the par vagum and the connection of the duodenum with the sympathetic centers, he is inclined to regard "peripheral irritation as the more probable factor in the disturbance of the glycogenic function. Brown-Sequard and others have well established the fact that reflex irritation is sufficient to arrest and prevent secretion, and, if continued long enough, to produce structural change of tissue."

#### TREATMENT.

In the detail of treatment founded upon these conclusions, he advises the taking of such foods only as can be digested in the stomach, thus allowing the duodenum to rest, and preventing congestion. For the control of reflex irritation morphin or chloroform three times a day is advised. The principle in view is not deprivation of the carbohydrates in the food given, for the sake of avoiding the excessive secretion of sugar, but to supply the diabetic with ample nutritive material, and at the same time afford the nidus of functional derangement the quiet essential to recovery of normal condition. The use, then, of codeia by the older physicians is seen to have a physiologic foundation, and, with our better comprehension of the procedure of digestion, we should be enabled to combine the principle of rest with the principle of appropriate feeding in treating diabetes and allied maladies more successfully.

Reviewing the points involved in the field I have traversed with such brevity, is it not clear that one factor in the vital economy of the human constitution has been much neglected, viz., the relation of the nervous system to digestion? Is it not a matter of oversight that heredity may be a causative factor of diabetes, or that a gouty diathesis has a relationship to its existence, or that there is a possible connection between it and a disordered pancreas, as Von Mering and Lepire appear to insist? Nevertheless, the chief objective in the management of diabetes is to bring about a better nutritive condition, an improved constitutional feeling, a more cheerful view of one's personal relations to life.

On this account have we not resorted to methods in treating dyspeptic cases that were either quite unnecessary or contributory to greater disturbance of the alimentary organism? Instead of inducing calm have we not considered it necessary to give excitants and stimulants to arouse the weak and atonic stomach, when what was really required by its nervous apparatus was rest? After all our generalizations we have not fathomed the mysteries of nutrition, and the fact remains that nature in the recesses of subconscious activity can better manage the procedure of tissue building and repair than we can with all the wonderful array of tonics, emulsions and extractions. If it be rational to "give the devil his due," it should be more reasonable to give the gastro-

intestinal system credit for capacity to do its own work, and not hastily or deliberately interpose obstacles to hamper or prevent its effort to serve us.

#### DISCUSSION.

DR. WINFIELD S. HALL, Chicago—I believe the recommendations of Dr. Drayton are in line with a general movement in the medical profession, namely, that of a very much less degree of medical interference and of giving Nature a chance. I am heartily in sympathy with his views regarding the giving of digested and partly digested foods. I believe the custom has the same deleterious effect upon the alimentary canal as that of putting an arm into a sling and expecting its muscles to develop. We can not develop the secretory glands if we furnish for them the substances which they ought to be allowed to secrete for themselves.

DR. H. S. DRAYTON, in reply—We are organized naturally to want those stuffs which we deem foods. We have different degrees of appetite, and it is impossible for anyone to determine the exact amount of food which should be placed within the stomach of an individual. Experiments have been made by many biologists without special result in this regard. We remember the case of a distinguished professor, Dr. Oliver Wendell Holmes. He lived for many years by rule. He did not reach the age of a centenarian, though he died an old man, to be sure, probably attaining the good age because of his method. We see men living beyond the period of Oliver Wendell Holmes who give little thought to the quantity of food that they should eat. If we look over the array of old men in this country we would find that the majority belong to the class who are indifferent as to the quality and quantity of food which they take from day to day, and certainly quite indifferent to the scientific relations of their food.

#### LIVING ON BREAD.\*

ALEXANDER HAIG, M.A., M.D. OXON., F.R.C.P. LOND.

Author of "Uric Acid as a Factor in the Causation of Disease."

LONDON, ENG.

There are several forms of the uric acid free diet as I have elsewhere mentioned,<sup>1</sup> such as: 1, that which consists of milk, cheese, potatoes and fruit, and contains no bread; 2, that which contains these things with more or less bread and breadstuffs, and 3, the form with which I am concerned to-day, in which bread and breadstuffs form the chief sources of nourishment and a small quantity of fruit and vegetables are taken merely as sauces for the bread.

For the sake of comparison I shall give the approximate quantities required in each of these diets for a man of 140 pounds weight, who is supposed to be young and leading an active life, and therefore requiring a rather full diet, one that will yield 3.3 grs. of urea per pound of body weight per day.

The milk, cheese, potato and fruit diet for this man would be about:

|                  | Per cent.  | albumin. | Albumin.   |
|------------------|------------|----------|------------|
| 2½ oz. cheese    | containing | 33       | = 350 grs. |
| 3 pints milk,    | "          | 3        | = 787 "    |
| 15 oz. potatoes, | "          | 2        | = 126 "    |
| 16 oz. fruit,    | "          | 2        | = 137 "    |
| Total .....      |            |          | 1400 grs.  |

We see at once that this is a diet containing a large amount of fluid, and that nearly all the nourishment is obtained from the milk and cheese.

The mixed diet might be:

\* Read at the Fifty-second Annual Meeting of the American Medical Association in the Section on Physiology and Dietetics, and approved for publication by the Executive Committee.

1. "Diet and Food," J. & A. Churchill, London, 3d Ed., 1901.

|                             | Per cent.<br>albumin. | Albumin.  |
|-----------------------------|-----------------------|-----------|
| 10 oz. bread,               | 8 =                   | 340 grs.  |
| 2 oz. oatmeal,              | 12 =                  | 104 "     |
| 2 pints milk,               | 3 =                   | 525 "     |
| 1½ oz. cheese,              | 33 =                  | 210 "     |
| 1 oz. nuts,                 | 16 =                  | 68 "      |
| 18 oz. fruit and vegetables | 2 =                   | 153 "     |
| Total .....                 |                       | 1400 grs. |

And lastly the diet with which I am now specially concerned might be for the same man:

|                               | Per cent.<br>albumin. | Albumin.  |
|-------------------------------|-----------------------|-----------|
| 11 oz. bread,                 | 8 =                   | 340 grs.  |

The bread may be taken chiefly as toast, or, like the rice and macaroni, it may be made into pudding.

A biscuit may be eaten after the meals, simply carried in the pocket and eaten between times, when there is an appetite. This is one of the points with regard to such a diet, that toast biscuits and similar breadstuffs can be eaten almost all day long without strict attention to meal times; they can be added after the meal is over or before the next meal is begun, in a way and to an extent that milk and cheese could not be used, without causing severe dyspepsia.

The oatmeal may be taken as porridge twice a day, and it should be thoroughly well cooked, not ten minutes or twenty minutes, but it should be placed in a double kettle and left on the fire or by the side of it all day. The same is true of rice and macaroni; they can not be too well cooked.

The porridge may be mixed with a liberal allowance of butter and some salt, though others may prefer sugar. The rice may be eaten with olive oil and salt, or with fruit or jam. The potatoes may be mixed with oil or butter and eaten with the bread, biscuits and cereals; or other vegetables in season may be substituted for them and used in the same way. The fruit may be taken with the bread and cereals, either raw or cooked, or as jam, or in puddings.

No doubt there are many who can not at once take as much bread and breadstuffs as are here given, and I myself, when a meat eater, used to be a great meat eater, and rarely took more than three or four ounces of breadstuffs in a day. But the habit of eating larger quantities can be gradually acquired, and I myself can now manage sixteen ounces a day without difficulty.

Those who can not take the above quantities of bread and cereal foods must take a little milk and cheese, say: one ounce cheese, 33 per cent. or 140 grains albumin; one pint milk, 3 per cent. or 262 grains albumin, a total of 402 grains, and then take sufficient cereal foods to supply 1000 grains of albumin.

Though I can not do it myself, there are some who can live on the above breadstuff diet, which, of course, can be modified by substituting other cereals in ways I have no space to mention, and my experience seems to show that those who do live on such a diet, or even on its modified form, with a little milk and cheese, gain several important advantages. First of all, many people are unable to take much milk and cheese, partly because they do not like them, partly because they fail to digest

them; while bread is a much more important article of diet all the world over. It is more generally eaten and to a larger extent than any animal food, and it is only in a comparatively small part of certain countries, chiefly in Europe and America, where the diet has come to consist almost entirely of flesh, that bread has come to be but little used. It has long appeared to me that this which is pre-eminently the food of man is deserving of study and attention.

Then milk and cheese, if taken beyond quite small quantities, may undoubtedly cause constipation and pale, powdery evacuations, which are so hard as to increase the discomforts of piles, from which meat eaters so often suffer, and even to tear the mucous membrane at the anal orifice. Milk especially, under the conditions which attend its distribution in large towns, is a vehicle for many diseases, and to be rendered even moderately safe must be boiled or sterilized. Again, milk in any quantity, as when two to three pints per day are taken, may cause dyspepsia from a mere excess of fluid; this tends to dilate the stomach, it dilutes the gastric and intestinal juices, and the result is that fermentation and dyspepsia may take the place of digestion.

Similar unfortunate results are produced by the silly practice of putting in uric acid containing foods with one hand, and trying with the other to wash out the excess of this substance by copious libations of fluid far in excess of thirst and its demands. As I have for years been pointing out, it is far better to leave the uric acid outside the body, and then there will be no need to dilate the stomach—as the Germans are said to do with excess of beer—or gorge the blood vessels and even dilate the heart with fluids for which there is no necessity, and which are, after all, of but very little use in eliminating uric acid.

So far as I know there is but one rule: Eat when you are hungry and drink when you are thirsty; and if you go beyond this you are certain to suffer; but to introduce unnecessary uric acid and then to try to wash it out with unnecessary water is to pile suffering upon suffering, even to the destruction of life itself.

Similarly in disease, as in the high blood pressure conditions from which flesh eaters and tea drinkers so frequently suffer, it is little short of insane to pour in fluids in excess of the demands of thirst. Look at these poor sufferers, how they improve on a drug that frees the capillaries and lowers blood pressure and allows of a diuresis; see how they improve further on a purge of calomel and colocynth that sweeps out a few pints of fluid from the intestines. And yet the very people who have watched this improvement may go on in thoughtless routine to pour into the patient hour after hour ounces of fluid in excess of the requirements of the body, far in excess of thirst, for in such cases there is often none, with the result that they dilate the stomach, gorge the vessels and increase the dilatation of the heart, which it was their object to diminish.

The great advantage of the bread diet in certain conditions of dyspepsia, and especially in conditions of high blood pressure, morbus cordis, and dilated heart, is that it is a dry diet; that the fluid taken can be reduced to one and one-half pints or even one pint in twenty-four hours, till nature asks for more by making the patient thirsty, and then alone can we be sure that we are not giving too much. The great point in the taking of breadstuffs and that which prevents them from causing dyspepsia, is their thorough and complete mixing with the saliva in the mouth; and this is greatly facilitated by taking them in a dry state except for a little butter. And

for this reason dry breadstuffs, as toasted bread, biscuits, rusks, into which the saliva can penetrate easily, are much more readily and certainly digested than such things as new bread, bread and milk, porridges or milky puddings, into which the saliva can only get slowly and with difficulty and after more or less dilution with other fluids.

There are some people who can take breadstuffs in any of these conditions and digest them without difficulty or dyspepsia, but those who do suffer should remember to take them only in that condition in which complete mixing with the saliva is possible and easy; dry breadstuffs can generally be taken by every one and eaten at irregular hours and between meals without dyspepsia. Even the possession of teeth is not necessary, for if dry breadstuffs are well sucked, they become completely mixed with saliva and softened by the aid of the tongue and gums. So that those whose teeth have been ruined by the fibers of meat and fish, for which nature never intended them, can continue to live on a breadstuff diet even without any teeth at all.

There is one other advantage of breadstuffs which I have also mentioned elsewhere, namely, their relatively slow digestion and metabolism, in virtue of which they give a steady supply of force and urea over a number of hours, thus accounting at least in part for the great powers of endurance shown by the animals that live on them.

And now I give a figure to illustrate one or two points with regard to this. It shows the hourly excretion of urea in grains on two days, which are placed on the same

Fig. 1.—Urea in grs. per hour.

paper for purposes of comparison. The curve AA shows the effect on the hourly excretion of urea of taking half a pint of milk at 8:30 a. m., no food or drink having been taken since the previous night. The curve BB shows the effect of taking at the same hour a nearly equivalent meal of albumins in the form of toast and biscuits with some water. The broken line CD shows the probable fall of urea if no food had been taken at 8:30, and is a continuation of the fall which was taking place from 7:30 to 8:30 as shown in the line BC.

The position of urea at 8:30 on these two mornings differed by some two grains, and the fall in urea that was taking place or that would have taken place if no food had been continued probably differed also. The absolute effect of the albumins taken as bread is the difference between the lines CD and CB, and the absolute effect of those taken as milk is the difference between AA and a relatively similar fall to that in CD. The object for which the figure is given is to draw attention to the fact that 130 grains of albumin taken as milk at 8:30 a. m. produce a much more rapid rise in the formation and excretion of urea than a similar

quantity of albumins taken as toast and biscuit, and that the rapid rise is followed by a rapid fall. It also shows that the albumins and force from milk are largely worked off in the first two hours after it is taken, while those from breadstuffs are spread over a longer period; the rise is slower and continued longer.

As I have elsewhere said, those who get their albumins from milk are in the position of a motor supplied with a quick burning oil which gives out great force for the first two hours, but is sooner at the end of its resources, while those who get albumins from breadstuffs can not produce so much force in the first two hours, but will be able to go on longer.

This is a part of the physiology that lies behind the superior powers of endurance shown by grain-eating animals; for, as I have for some years been pointing out,<sup>2</sup> strength and power rise with rising urea, and fall with falling urea, and, in fact, are in all conditions proportional to urea; so that the collapse that follows on severe dyspepsia or shock, is little more than the suspension of absorption of albumins from the stomach, with the consequent suspension of the formation of force and urea. The digestion and metabolism of flesh much resembles that of milk, hence the lion and tiger can give out enormous force over a relatively short period of time, while the elephant, the bull or the horse can outlast them, and perhaps produce even more absolute force in a longer period.

This is probably what patients mean when they say—and it is, I think, a common experience—that a meal of breadstuffs lasts longer than a meal of meat; for with falling urea and diminished force production, the need for more albumins is felt as hunger. This may come after a meal of milk or flesh, say in three hours, but after a meal of similar albumin value in the breadstuffs, not for four hours.

Breadstuffs form a very convenient diet for those who are moving about the world, for they can be obtained almost anywhere, while milk and cheese it is often difficult or impossible to get. Breadstuffs also can, if necessary, be conveniently carried in the form of grain, meal, rice, macaroni or biscuits.

These cereals have been the foods of mankind in the past, and they are still the foods of the great majority, and only in parts of a few countries where flesh eating has been carried to great excess, have they fallen somewhat into the background. But here, as elsewhere, the majority are right, and the minority pay an enormous price for their unnatural but stimulating food. Among the flesh eaters, disease and death are rampant, the natural term of human life is but rarely attained, and even the shortened life is too often rendered both useless and miserable.

Let any one who might at first sight be disposed to doubt this statement observe for himself how many meat eaters and tea drinkers between the ages of 17 and 23 have normal blood, not merely normal as compared with a standard fixed by meat eaters, but normal as compared with that of those of the same age who have never touched meats. Let him observe how many flesh-eaters from the age of 45 onwards have either normal blood or normal circulation, and do not suffer either from dyspepsia, depression and insomnia on the one hand, or from arthritis, lumbago, sciatica or bronchitis on the other—not to mention Bright's disease and diabetes.

#### DISCUSSION.

DR. WINFIELD S. HALL, Chicago—I believe that one could

2. "Diet and Food," Ed. 1, 1898, Ch. 1.

scarcely have kept track of the rapidly growing literature of this question of the influence of the metabolism of nitrogenous food upon the general nutrition without being impressed with the effect that in the vast majority of cases in England and America the general custom is to take too much nitrogenous food—too much meat. It seems to me that there are two rather antagonistic positions taken in Dr. Haig's paper. I can not reconcile his statement concerning the perfect parallelism of nitrogenous ingesta and egesta with varying muscular force and work capacity, with his insistence upon a bread diet. Bread diet is largely a carbonaceous food and has to be taken in very considerable quantities to get a sufficient amount of albumin. The muscular power varies largely with the oxid of the carbonaceous rather than of the nitrogenous element. The nitrogenous element is, I consider, absolutely essential up to a certain amount. After that it is excreted or oxidized day by day, so that the nitrogenous excreta after a certain minimum is going to vary with the nitrogenous ingesta. This maintains the nitrogenous equilibrium. I have read nearly all that Dr. Haig has written, and am in sympathy in general with his opinions. I wish sincerely that he were here, for I believe he would clear up this which seems to be an ambiguity in his presentation of the subject.

DR. DAVID PAULSON, Chicago.—It is surprising how little attention the medical profession gives to the subject of practical dietetics. We have been so busy studying pathology and surgery that we have but little time to give to dietetics, the very neglect of which is causing so much material for pathological study. Something which Dr. Haig wrote several years ago led me to undertake some experiments to determine whether or not the quantities set down in the ordinary text-books were not in excess of the real amount required by the human system. I, therefore, selected ten medical students and had them weigh the exact amount of fully toasted bread consumed each day for two weeks. The majority of this class of ten students were young men and women who were working their way through medical college. The average amount consumed was 16 ounces a day of nearly water-dry bread. Every member of the class gained in weight, some as much as three pounds on 16 ounces of bread a day. A second experiment was undertaken upon nearly 300 healthy young people, and it was found that they consumed on the average 16 ounces of starch, 2.8 ounces nitrogenous food, and 1.5 ounces of fat; this investigation was continued for several weeks. It may be fairly assumed that this is not far from the normal proportions, as these young people selected the food for themselves from an extensive bill of fare. Their weight was taken at the end of each week, and the entire experiment was conducted with the most careful and scientific accuracy by the Battle Creek Sanitarium Laboratory of Hygiene. It was shown from this that the figures set down by Pettenkofer and others are entirely too large for us to follow, in this country at least, and, secondly, that we normally use a larger amount of carbonaceous food than has been generally supposed. One part nitrogenous to four parts carbonaceous, as has been suggested by some, is certainly altogether too high. This tends to overstock the system with nitrogenous food elements and tends to produce the uric acid diathesis. I do not agree with all Dr. Haig's conclusions, yet I do believe that the medical profession is greatly indebted to him for the valuable researches that he has made in dietetic lines. I have been interested in noticing the power of endurance possessed by persons who live on a uric-acid-free diet. It has been my fortune to study some of the leading long distance runners, etc., and a number of the most successful of them live upon an entirely non-flesh dietary. The long-distance bicyclist, Nelson, is, I believe, a vegetarian. In these long distance races the flesh-eaters will generally lead for a short time, but the non-flesh eaters will almost invariably out-distance them, and get off their bicycles as though they had had no special exertion, while the others often have to be assisted. Another cyclist who a few years ago made a large number of successful long-distance records used no meat, nor tea, nor coffee. He stated to me that when he started out on short-distance runs the meat-eaters could out-distance him, but when they had reached the last ten or fifteen miles they would be nearly used up, while he would be almost as fresh

as when he had ridden only fifteen or twenty miles. I have been much interested in metabolism of nitrogens, and believe that there is much more to this subject than we now see. I hope we shall soon acquire more definite and satisfactory knowledge in this direction.

DR. JAMES PUTNEY, Charleston, W. Va.—It seems to me as if Dr. Haig were seeking to secure recognition of facts which physiologists have recognized for some time. The average of nitrogenous food is given as 100 grams per day. In the interesting account which Dr. Paulson has given us we see that the students live upon 16 ounces of bread per day, about 2 ounces of nitrogenous material. This is not so much out of the way so far as statistics go. It seems to me, too, that Dr. Haig is taking a one-sided view in his remarks about uric acid results. It is well recognized to-day that there are two classes of uric acid cases—cases of dietetic origin, and cases of tissue destruction origin. I question whether the larger class is not the latter. It is true that we find among those people whose muscular exercise is deficient a tendency to ingest excessive quantities of food. This gives rise to the assumption that disorders of the nitrogenous metabolism are due to that fact. It should also be remembered that there is an equality in the gastric function. Nothing is better recognized to-day than the fact of the breaking down of the leucocytes attended with the development of uric acid. This indicates the distinction between those cases of nitrogenous disorders of metabolism traceable to the short cut, which the nitrogenous elements of food in excess take and the long course which the nitrogenous metabolism of tissues involves. As an illustrated case on this I want to submit the following: Mr. G., 59 years, full habits, temperate, good history, when he partook of full meat diet suffered most intense headaches and would be in bed for a day or so. With meat diet cut off, he would not have attacks until he returned to meat diet again.

THE CHAIRMAN, DR. CHARLES M. HAZEN, Richmond, Va.—I fancy Dr. Haig wishes most of all to insist upon a vegetable source of albumin, so as to get rid of ready-formed uric acid and other waste nitrogenous matter. In a recent monograph by Dr. Mallet, of the University of Virginia, it is shown conclusively that such products as kreatin and kreatinin whenever present in meats simply load up the system with proteid material of no value whatever. The point was touched upon in our discussion of the last paper in connection with food products from animals, in which it was stated that exhausted beef could not furnish proteids suitable for food.

## METAMORPHOPSIA VARIANS.\*

WILLIAM H. DUDLEY, M.D.

OPHTHALMIC AND AURAL SURGEON TO THE EASTON HOSPITAL.  
EASTON, PA.

It is possible in presenting this subject that the writer is simply going over ground that has been well covered before; though, with the endeavor to find some reference to it during the past five years, I have left no opportunity unimproved to do so, and yet without success. In fact, the subject of metamorphopsia, except that caused by the correction of astigmatism, has received but very little attention by any writer on ophthalmology to whose works I have had access; and if the cases of this variety are as uncommon as I am led to believe, the following may prove of some interest.

On June 6, 1896, while examining C. F., aged 45, for his refraction, and when obtaining his best vision with his right eye, he remarked that it was difficult to make out the line—the 30-foot line—on account of the rapid movement of the letters. He stated that they would approach each other, and again separate quite rapidly, and that the different letters of the line were continually moving up and down in an extremely irregular manner,

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Würdemann.

and at the same time the outline of the various letters were undergoing continual change.

Inasmuch as this patient was a man of more than ordinary intelligence, occupying the position of superintendent of the erecting department of one of our large railroad repair shops, I felt bound to pay some attention to his statements and investigate the subject somewhat farther.

I will state here that the left eye was found normal, with the exception of a moderate amount of hyperopia, which when corrected with +1.25 D.S., saw 20/20+, and that in binocular vision, no metamorphopsia was present.

The right eye was then placed under full mydriasis, and the various anatomical parts studied separately. The cornea showed no variations from the normal, by focused or reflected light, and although a mechanic, it showed no maculæ caused by foreign bodies, which such patients are likely to present. Examined by the Javal ophthalmometer, model 1889, it showed one-half diopter of astigmatism with the axis  $105^\circ$ , but perfectly regular;

eye was equally negative. The appearance of the optic disc, distribution of blood vessels, as well as the macula, were entirely free from any abnormality.

In observing the diagrams, the left-hand column represents the original figures, the remainder, those seen by the patient.

The changes which were said to take place in certain outlines were now studied, and he was directed to do this at a distance of fifteen feet, and was asked to record on a tablet some of the changes which these various outlines underwent. At first he was directed to look, with the left eye covered, at a 100-foot L, when the letter took on the various changes represented on the diagram. Next he was asked to look at two parallel lines 100 millimeters long and 25 millimeters apart, with a small cross in the center between them, when all and many more of the changes here represented took place. I will state here that all of these drawings are copies of those made by the patient himself, while the examination was being made.

He was then directed to observe a double cross, with a small cross in the center, of the same general dimensions as the former figure, with the result that all the lines underwent rather rapid changes in their shape and direction; sometimes the vertical lines were more affected, and sometimes the horizontal, and sometimes they were all affected at once, as will be observed in the diagrams. He was then directed to look in succession at a vertical line, about 10 centimeters long, with a small cross at its middle; a circle 6 centimeters in diameter, with a dot in its center; a square 4 centimeters across, with a small cross in its center, and a diagonal square of about the same dimensions as the previous figures, fixing his vision on the small cross, and the distorted figures here shown are a few of the shapes these figures presented.

This examination was made both with and without his glasses on; with his pupils wide; and also with his accommodation intact, and the result was always the same.

These observations were continued with the patient looking through a stenopeic slit, and the pinhole disc, when the result was the same, with the exception that the changes were much slower. Various colored glasses were also used, and the only difference observed was a reduction of the rapidity of the changes; and it appeared to make no difference by what means the reduction of light entering the eye was obtained, whether by the stenopeic slit, the pinhole or by colored glass, or by glass of different colors so far as my observations went.

The reduction of the frequency of the changes by reducing the amount of light entering the eye was utilized in making the diagrams; for with full illumination the rapidity of changes was so great that it was very difficult to carry the impression long enough to record it on paper, while with a colored glass, or a narrow slit, it could be done much more readily.

In order to determine the area of this metamorphopsic region, the patient was directed to look at the various corners of one of the large diagrams and the metamorphopsia was found to extend a little over a degree in either direction, which is about as far from the point of fixation as the average individual would be able to state whether a line was straight or curved, especially with the added confusion of constantly changing position of the lines in the intervening space.

CASE 2.—Mr. J. H. M., aged 50, consulted me May 24, 1897, in reference to his refraction. The same methods of examination described in the previous case were used in this, but no lesion or physiological peculiarity in any of the refractive media or fundus could be made out.

all the circles and radiating lines on the large disc of this instrument were perfect.

In using the skiascopic mirror, no irregularities of the refractive media could be made out. The aqueous was clear, and the lens was transparent throughout.

The lens was now examined for possible irregularity of outline, or density, or the possibility of a lenticulus; but the reverse shadow at the point of greatest refraction, which is present in these cases, was absent, as well as the wheel-like motion, which is observed in the shadow, where the central portion of the illuminated area has a greater degree of refraction than that surrounding it; in short, the skiascope revealed nothing unusual in an eye with +.75 D.S. and +.50 D.C. axis  $105^\circ$ , which was his proper correction.

Neither the plain mirror nor the ophthalmoscope showed any variation from the normal in the appearance of the vitreous, which was absolutely clear throughout. The result of the examination of the background of the

While examining his right eye for his distance vision he complained that the letters did not retain their shapes or positions in the line, and that some of them would disappear, to return an instant later; others would move up and down about one-half their height, but not much sideways.

This gentleman is a merchant, though at times he has paid considerable attention to landscape drawing and painting, and was, therefore, able to reproduce on paper quite accurately what he saw.

In going over the subject with him I used the same diagrams which were used in the previous case, and the accompanying drawings represent as nearly as possible some of the forms which these figures took on. While looking at a word at reading distance one or two of the letters in the center of the word would move up, and the whole word would be likely to form a curve, with its convexity up, to remain but an instant, and then to return to take on some other unusual form. In studying

therefore unnecessary to repeat here. The result was negative so far as the eye itself was concerned, but inasmuch as there were some points so unlike the others they may be described. For example: while looking at the circle, it appeared to elongate; then a constriction would appear near the center, when it will appear for an instant like a figure 8, and sometimes with a dot in both circles and sometimes not.

While looking at the vertical line with the cross, the cross would curve sometimes up and sometimes down, and at the same time would appear double, and the two cross lines would approach and become one, and again separate. In looking at the square with the dot in the center, this figure would undergo many of the changes observed in the circle; it would elongate and sometimes become contracted in the center and sometimes not, and also would occasionally have two dots, one in the upper and one in the lower part.

In studying the diamond-shaped figure it sometimes took on nearly the figure of 8 form, as in the square and circle, but when looking at the left corner of the

these figures, it will be noticed that the horizontal lines are the ones most affected, while the vertical lines changed but little.

As this patient's home is several hundred miles from Easton, it has been impossible to obtain but a single opportunity of studying his case; by correspondence, however, I learned a year or so after my examination, that whenever he used the right eye alone the same varying metamorphopsia was present.

CASE 3.—Mr. G. M. R., aged 57, came June 23, 1898, for an examination of his eyes, and here again while examining his right eye, the patient complained of the letters moving about and changing their shapes.

As this gentleman, like the others, was a man of more than ordinary intelligence, a member of a large wholesale firm in the town, I felt I might rely upon his statements, and accordingly went through all the various methods of examination as in the previous cases, and

diamond, the upper left and the lower right lines take on convex curves without the other side lines being seen at all.

In order to determine the actual extent of the metamorphopsic region, he was requested to look at the center of a card with radiating lines, and was asked to observe how far these lines were affected from the point of fixation, and a careful measurement showed the area to cover about one degree, or thirty minutes either way from the point of fixation.

In observing the changes which took place in the various figures, this patient stated that when he gazed steadily at a figure for a few seconds it would go through certain changes for the period of a few seconds, when the changes would cease and remain stationary till the point of fixation was changed a little or he winked, when the process was set in motion again.

In this case, as in No. 1, the reduction of the intensity

of light was followed by a reduced frequency of the changes, and was made use of in the same manner in making the diagrams. In this case the vision of the affected eye was 20/40 and was not improved by glasses; in fact, by skiascopy the eye appeared emmetropic, and doubtless without the metamorphopsia it would have had full acuity of vision. In this case also the left eye was emmetropic and vision normal.

This patient feels that he is able to fix pretty accurately the time when this disturbance began; he states that when about 15 years old he began to shoot with the rifle and became something of a crack shot, but at about 25 years of age he found he could hit nothing, became discouraged and gave up the rifle, though he did not know that the eye did not see as well as the other till becoming presbyopic and was examined for glasses.

In reference to the cause of the peculiar changes which these outlines undergo when observed by these patients, I have endeavored to settle the question as nearly as possible in reference to the refractive media, and it seems to the writer that pathological changes and physiological peculiarities of this region can be eliminated, as cause of the metamorphopsia.

At first I was inclined to believe that the location of this disturbance must be central, but upon more careful study of reported cases of hemianopsia it seems that those due to destruction of the visual center of one side, the vision at the macula has been preserved on both sides, which if true, would leave but one location for the disturbance, viz., in the retina, and this of a form not producing ophthalmoscopic lesion.

It may be suggested that some small lesion of the retina producing a metamorphopsia, being accompanied with a small amount of nystagmus, might be held responsible for this visual disturbance. In endeavoring to settle this question I had Case 3 look through the Maddox groove, and it did not show the rapid oscillation of the line which one might expect, if a nystagmus existed; though I am of the opinion that in some cases of monocular nystagmus this disappears in binocular vision, which would render this test invalid. I may also state that in examining these cases with the ophthalmometer there was no oscillation observable.

It is now five years since my observations began with the first case and three years since Case 3 was first examined, and recent examination of both of these cases shows the same varying form of metamorphopsia to exist.

It will be noticed that all three cases were males; in each the right eye is the one affected; and inasmuch as they were unable to get the metamorphopsia in binocular vision, neither became aware of his defect till about the time he became presbyopic and had his eyes tested separately.

#### DISCUSSION.

DR. S. D. RISLEY, Philadelphia.—The very careful and elaborate study Dr. Dudley has made of his cases removes the paper from the realm of discussion since all conceivable causes of metamorphopsia seems to have been excluded. I am inclined to believe that minor grades of metamorphopsia are not so rare as would seem to be indicated in literature, but I have always been able to discover its cause. The chief interest in Dr. Dudley's cases therefore seems to center about the absence of any explanation for the distortion of the images, in the three instances he has presented for consideration.

DR. G. C. SAVAGE, Nashville, Tenn.—In the cases of metamorphopsia presented to us in his paper, Dr. Dudley has considered that the cause could be either refractive, retinal or mental. By means of retinoscopy he was not able to find any refractive cause that would account for the metamorphopsia. With the ophthalmoscope he was not able to find any changes

in the fundus. He was, therefore, almost forced to the conclusion that the metamorphopsia was mental. I do not agree with the Doctor that there are three causes for metamorphopsia. The one of his three that I would leave entirely out of the question would be the mental. I do not believe that there is a mental metamorphopsia. If there had been a refractive trouble in either of his cases that could have caused the visual changes, he would have detected same by means of the retinoscope. I believe it possible for retinal changes to exist that would result in metamorphopsia without our being able to detect any thing wrong by means of the ophthalmoscope. In any thickening of the choroid behind the macula, whether that thickening be due to the exudation of serum or a deposit of plasma, there must of necessity be a disturbance in the relationship of the cones. Every cone and every rod should point towards the center of retinal curvature. LaConte has beautifully said that "the rods and cones see ends on." If these ends are pointed towards the center of retinal curvature there could be no metamorphopsia other than refractive, but if they be so disturbed that some point in one direction and some in another, then metamorphopsia must exist. We all know how patients complain of metamorphopsia when there is a beginning central choroiditis. If Dr. Dudley's cases had been congenital, I would be inclined to the idea of a loose arrangement of the rods and cones. The variableness of the metamorphopsia in his reported cases constitutes an interesting feature.

#### A PLEA FOR GREATER UNIFORMITY OF STRENGTH AND EXACTNESS IN OUR MEDICAL ARMAMENTARIUM.\*

C. F. WAHRER, M.D.

FT. MADISON, IOWA.

The subject of my paper may not be new to anyone here, and, like the longing for immortality and the fabled Fountain of Youth, may be somewhat utopian in its nature, yet we must not forget that keeping eternally at it has often been followed by good results.

We certainly can not admire Shakespeare for the originality of his subject-matter, for everything he wrote was either old history or romance before he was born, but the manner in which he put it, and the way he said things and made his hearers and readers feel it, there is where Shakespeare is great. So if I can impress you with what I have to say in such a manner that you can all feel it, and so it will do good, my ambition will be satisfied.

We are all aware that in the good old days we guessed at many things, at diagnosis, at etiology, at pathology if it was considered at all, and also at the therapeutics that entered into our treatment. We do some of these things better now. We diagnose almost perfectly, by means of instruments of precision, by reasoning, by an improved symptomatology, by bacterial and chemical tests, by reflexes and many other means. The microscope also aids in our pathology, which in many instances we may call perfect. We know more of the etiology of diseases and this alone also suggests the treatment. Of these achievements we are not only reasonably proud, but feel that we are peculiarly blessed that we live in this x-ray age, so full of possibilities for us all. But in one thing still much, very much indeed, is desired, and that is after all the main thing, namely, our therapeutic means of combating disease. We may be somewhat blinded by the fact that the number of our remedies is wonderfully increased. Many old and use-

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. Thomas Hunt Stucky, Leon L. Solomon and N. S. Davis, Jr.

less remedies are now no more used, toads' eyes, lizards' tails and bats' wings, and the blood of black cats, bugs and other vermin are no more the source of our therapeutic resources; neither do we now use metal tractors to draw out the diseases, nor do we any more depend upon the royal touch, nor fear witches nor the evil eye. Osteopathy, christian science and absent treatment have replaced all these.

Notwithstanding all this, I want to ask you seriously, has this branch of medicine, namely, *materia medica*, as far as real merit of the matter that enters into our remedies, kept step with the rapid advancement of other departments of the healing art? I believe I must answer this negatively; not because chemists and pharmacists have been idle, neither has experimental therapeutics been slow to come to our aid, for, as before said, many new and really valuable remedies have been discovered, old ones replaced by better ones, or new uses found for the old ones, but we have not paid sufficient attention to the quality of the goods we use in fighting disease.

You know by this time that fluid extract of ergot varies as one to fifty, gelsemium the same, that cannabis indica varies all the way from nothing up to the most lethal and intoxicating character, while opium, digitalis and ipecac, the latter now almost extinct, vary from two to a hundred fold, not only in the finished product, but in the original drug, depending on locality of growth, methods used in preservation, age, and finally, in preparation. Even the rules of the pharmacopeia are faulty in giving us drugs of uniform strength, especially when we consider the fluid extracts, the solid and powdered extracts, tinctures, elixirs and other forms made from these. If to all this we add the cupidity and dishonesty and ignorance of many manufacturers, and the insufficient laws governing the output of their laboratories, and augment this by ignorant, dishonest druggists, and often careless and sometimes ignorant prescribers, the outlook for the sick man is anything but cheerful. I hope I shall never get sick.

Now what is the use of making a diagnosis which entails so much study and worry? We auscultate, percuss, and look through the microscope; we analyze blood, urine, and sputum; we make bacteriological cultures, and test eyes, hearing, and the reflexes; we palpate; we explore with the *x-ray*, sounds, specula, meatoscopes, laryngoscopes, and otoscopes; we catheterize ureters, and a few of us, at least, examine the fundus of the eye with an ophthalmoscope, and in fact, what do we not do to a patient? Well, we finally arrive at a diagnosis. We know what is the matter; then we begin to prescribe, and the trouble begins.

Without going into details and naming the drugs that fail in relieving a given symptom, I just desire to say, that it may be put down as an axiom that good, well-made medicines when applied by a wise physician, usually respond as we desire, and, when they do not and we feel sure of our diagnosis, the blame properly rests with the preparation we use. This calls, on our part, for preparations made according to some uniform standard, by an honest, upright manufacturer, who has a proper pride, coupled with a sensitive conscience, in his business; one who feels that human life and happiness depend upon him as much as they depend upon the doctor who uses his products. He should feel that his is a high calling, not only for the dollar and dime, but also for that noble cause that makes life worth living. But since there are almost thousands who are the opposite, who have only the commercial side in view, we must use

only such products, in the absence of suitable laws to protect us and our patients, as we know are reliable either in their very nature, or by the guarantee of the manufacturer.

Of the first class are the alkaloids, glucosids, and well-known mineral derivatives. Such alkaloids as morphin, quinin, cinchonidin, strychnin, cocain, atropin, and the glucosids, like digitonin, digitalin and others; the mineral salts, like calomel, iron, sulphur, silver, and others we know, are more reliable than are the crude drugs from which they are made, or any of their pharmacal preparations, especially when made by unscrupulous manufacturers. And when these same unscrupulous men offer us polypharmaceutical mixtures of the handorgan and shotgun variety, we are all the more at sea. Why should any physician allow some fake manufacturing firm to prescribe for him some anti-phthisine, anti-pneumone, anti-dyspepsin, or anti-febrin, that has not even a qualitative label on it, and if it pretends to have, it is only partly so—saying it contains 1 per cent. iron, 2 per cent. quinin and other valuable ingredients, mixed in a menstruum of which we are the sole patients. Thousands of such mixtures are offered physicians daily in their offices by wily sample fiends who are sent out by these vampire manufacturers. The worst of all is, that the profession buy these slops, and even give testimonials, many of them signed by Pro. Big Medicine man of the College of Physicians and Surgeons of Sodom and Gomorrah, who recommended them to his classes and could not practice medicine without them.

Every professor in a medical college who gives such testimonials to proprietary and polypharmaceutical nostrums should be promptly dismissed from his chair; then let him give his undivided attention to the nostrum mill of which he is undoubtedly a silent partner.

There is a whole city full of prominent doctors somewhere on the banks of the Mississippi, nearly every one of whom has given testimonials to poppyine, anti-somnia, or Teapot's chlorids. And there are others! I am glad to state, however, that we have a few who strive for higher things, and these should be encouraged.

Merck of Darmstadt, Germany, and such as Parke, Davis & Co., of Detroit, Mich., are striving to prepare drugs and medicaments that are of standard strength and uniformity. These goods they call standardized, and the process, standardization. With some products they accomplish this by filling them to a certain percentage with their active principles, and where such is not possible, to test them physiologically on animals and control experiments.

If we encourage the manufacturers of such goods, and use whenever we can alkaloids and mineral products and their uniform salts, looking to quality and never to price, and ask for similar laws to the pure food laws enacted in some of the states and some foreign countries, we can then hope for a better state of things, and a more cheerful outlook for the sick man. This might be brought about also in a measure by just such bodies as the great American Medical Association. Let a committee be appointed to memorialize the committee that revises the pharmacopeia, to introduce better and surer methods in the manufacture of medicines; also let it memorialize Congress to give us laws to protect the consumer of drugs, the same, at least, as protects the butter eater from oleomargarine. Such a committee may finally accomplish something.

As long as we use uncertain missiles, at uncertain distances, with the uncertain hope that something may do some good, I see no use in drilling our medical recruits

for four or five years, at an immense expense of money and energy, unless we can equip them at the end of that time with a more exact and uniform armamentarium. Remember you may possess the diagnostic ability of a Flint, an Osler or a Loomis, the therapeutic knowledge of an Eichhorst, Wood or Hare, and yet all this ability is perfectly helpless in the presence of inert drugs and dishonest medical purveyors and manufacturers.

However, declamation is useless. Let us do something and keep at it till we succeed. Much of the present evil is due to the fact that many doctors do not study their texts on *materia medica* as assiduously as when they crammed for their diplomas, but they read trade journals and floating literature on semi-proprietary preparations, whose virtues are extolled by their exploiters. These are little less than common nostrums, and are only combinations of well-known ingredients, one of which is usually some form of alcohol. Let us all stop this, study more faithfully our *materia medica*, the physiologic action of medicines, and their bearing upon pathologic lesions, and in a short time much of this evil will pass away. Only when we ask for better things can we hope to get them.

## STANDARDIZATION OF CRUDE DRUGS AND GALENICAL PREPARATIONS.\*

ALBERT B. LYONS, M.D.

DETROIT, MICH.

Does a given quantity of any medicinal agent produce under similar conditions approximately the same therapeutic or toxic effects? There can be but one answer to this question, and that an affirmative one. Granted that individual susceptibility shows surprisingly wide variations, and that vital reactions are profoundly modified by accidental causes, not always obvious, it remains true that from a certain dose of any potent drug we expect to obtain certain definite results, which we regard necessary for the restoration of our patient to a normal status.

It is true that in adjusting the dose in each particular instance, we take into account the factors of age, sex, general physical condition and known idiosyncrasy on the part of the patient; the very fact that we do this places emphasis on our conviction that a given dose will produce in a normal subject reactions of a definite known kind and degree. In other words, we assume that the medicine we prescribe is uniform in activity.

When that medicine is a definite chemical compound we may have confidence that one grain or one gram of it will under identical conditions produce identical effects, provided, of course, that the remedy itself is exhibited in the same physical condition in each instance—an important proviso sometimes.

A large proportion, however, of the drugs we prescribe are not of definite chemical composition. Such remedies as opium, henbane, *nux vomica*, *digitalis* and ergot consist of crude products of the vegetable kingdom, containing variable proportions of certain active constituents. The most of us find it still necessary to use this class of remedies in our practice. They constitute, indeed, the greater proportion of our *materia medica*, and claim and receive recognition in all the pharmacopeias of the world.

Many of them, it is true, contain definite active constituents which we also employ—in some cases almost

to the exclusion of the drug from which they are derived. We no longer prescribe Peruvian bark as an antiperiodic; quinin is every way better. We use constantly strychnin, atropin, morphin, codein, etc., where, a generation or two ago, we should have had no choice but to prescribe the crude drugs from which these alkaloids are respectively prepared. There are not wanting those who insist that scientific medication requires that we abandon altogether the use of crude drugs, or their galenical preparations, in favor of the active constituents to which is due in each case the therapeutic efficiency of the agent. That is the goal towards which we are tending, but it is a goal as yet far off. For another decade at least we must continue to depend to a large extent upon remedies compounded in Nature's laboratory. The pharmacopeia that must serve us for these ten years must still contain herbs, roots, barks, seeds and fluid extracts, tinctures and similar preparations, and we shall still be compelled to prescribe these if we are to give our patients the benefit of every resource of medication.

In the case of a number of valuable drugs, we have as yet no scientific method of determining beforehand the activity of a given sample. We do not know positively what is the active constituent, nor we have no means of determining with any precision how much of the known active constituent is present. We may judge something of the quality of the drug by its odor or by its taste. Otherwise we must find out what work it will do by actual trial. Must that trial be made upon our patients? Surely not, if it can be done in any other way. True, we may often feel our way in the use of a remedy without prejudice to the welfare of our patient, but the plan is one not to be adopted except in case of necessity. A very much better plan is that of trying the remedy upon some of the lower animals, condemning any which does not produce the effects recognized as those normally produced by the drug in question.

This, however, is a branch of my subject which I barely touch in passing. I wish rather to deal with the class of drugs that contain a definite known active principle, which can be easily isolated and quantitatively determined.

To what extent are drugs of this class found actually to vary in strength? That depends upon the drug. In the case of leaves, herbs and roots, it is common to find one sample two, three, five or even ten times as strong as another. The conditions under which the plant is grown, the season of collection, the length of time it has been kept in stock, the care or want of care that has been taken to guard it from the injurious effects of atmospheric moisture, all have their influence, greater or less, in the case of different drugs. The bark of a tree or shrub, particularly the root bark, shows less variation in strength, and less susceptibility to injury from moisture of the air, and seeds, provided they are properly ripened, are still more uniform and stable in composition; but even in the case of seeds, one sample may often be found to have twice the activity of another.

These facts have been better known generally to pharmacists than to physicians. Manufacturers of fluid extracts began, twenty years ago, to attempt to standardize some of their products by assay. The value of the principle was recognized at once by physicians, and the more progressive manufacturers have continuously improved their assay processes so that their products to-day are substantially uniform in strength, if susceptible of exact assay. Many of the assay processes in use by them are

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on *Materia Medica*, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. Thomas Hunt Stucky, Leon L. Solomon and N. S. Davis, Jr.

confessedly imperfect, yet even an imperfect method of standardization is better than none at all.

Our pharmacopeia is far behind the manufacturing pharmacists in this regard. The only crude drugs whose strength is regulated by assay in the pharmacopeia of 1890 are opium and cinchona bark. Crude opium must contain at least 9 per cent. of morphin; powdered opium not less than 13 per cent. nor more than 15 per cent., while cinchona bark must have not less than 5 per cent. of total alkaloids and at least 2.5 per cent. of quinin. The pharmacopeia provides also for jalap, the requirement that it shall contain at least 12 per cent. of resin, and for scammony that 75 per cent. of it shall be soluble in ether.

Owing to government supervision of importations of opium, the standard in the case of that drug has been reasonably well maintained. It is doubtful whether any particular attention has been paid to the standard for cinchona bark except by some of the manufacturing pharmacists and by a few conscientious retail druggists, unless it has been in some state like Ohio, where pharmacopeial standards have been enforced by local legislation. It is certain that jalap of pharmacopeial standard is hard to obtain anywhere.

The present pharmacopeia does not provide standards for preparations of cinchona, like the fluid extract and tincture, but it does so for the various galenical preparations of opium, except the camphorated tincture, and for those of *nux vomica*. The pharmacopeia of 1900, which will not be issued certainly much before 1903, will enlarge very greatly the list of drugs and galenicals for which standards are prescribed. It is safe to say that belladonna, coca, colchicum, hydrastis, ipecac and stramonium will be included in the new list, together with all their galenical preparations. In the case of *nux vomica*, the assay will determine the amount not of total alkaloids, as at present, but of strychnin, which is now recognized as practically the only active principle of the drug.

Unfortunately, standardization of drugs by physiologic or pharmacologic tests has been ruled out in the instructions given to the present pharmacopeial revision committee. While I recognize the fact that this class of tests necessarily lacks the mathematical exactness which is inseparable from a chemical assay, and, while I admit that there is a certain force in the objection that tests made on the lower animals may be very misleading with regard to the potency of a drug in its action on man, I am sure that standardization based upon these tests, in the case of drugs like these which are liable to be wholly worthless, is better than no standardization at all. If the pharmacologic tests are liable to be misleading, so also are many of the chemical tests. In most cases there are present several alkaloids differing widely in activity. An example of this is seen in *nux vomica*. Heretofore the total content of alkaloid has been taken as a measure of the value of the drug. Conclusions based on such an assay are correct only provided strychnin constitutes a certain fixed percentage of the total alkaloid. In fact, this is approximately true, so that it does not greatly matter whether you state that a given sample of the drug contains 3.2 per cent. of total alkaloid, or that it contains 1.45 per cent. of strychnin, if you remember that about 45 per cent. of the alkaloid is strychnin.

The practical difficulty is in separating accurately strychnin from brucine in the assay process. As yet the problem is not satisfactorily solved, and variations

amounting even to 10 per cent. of the whole amount are liable to occur in the determinations of strychnin made by different analysts. As close an approximation as that we might hope to make in assays by pharmacologic tests.

So in the assay of the mydriatic drugs. We know that in these drugs there exist two isometric alkaloids, hyoscyamin and atropin, besides other bases. We have no method of separating these two alkaloids where the total amount present weighs only a few milligrams—rarely as much as half a grain. We do not yet know accurately how these two alkaloids compare with one another qualitatively or quantitatively in activity, although that subject is now under investigation. It seems to me that it may be possible to judge as to the practical value of a sample of such a drug as belladonna almost as closely by testing the effects it produces on the eye as by a chemical assay. This statement will not seem so strange in the mouth of a chemist, when I say that in some test assays of belladonna leaves made recently by a number of experienced analysts using the same assay processes, results were obtained ranging from 0.24 to 0.41 per cent. of alkaloid, one result indeed falling below 0.20. This is, of course, an extreme case, but when so much is claimed for the exactness of chemical determinations, it is only right that such extreme instances should be taken into consideration.

That our pharmacopeia should so define every article of the official materia medica that prescribers can rely upon obtaining substantially uniform results from the remedies they employ, every one will admit, and this means that the principle of standardization should be adopted wherever it is applicable.

Several practical questions will arise, however, that admit of difference of opinion. The first of these concerns crude drugs. Shall we fix for these a definite, absolute standard, so that if a particular sample of the drug is either below or above that standard it must be rejected? Or shall we simply fix a minimum limit of strength, as we have done hitherto in the case of crude opium? The latter course seems to me to be the only practical one. It will be understood that such drugs are not to be administered in substance, but simply to be employed in the preparation of standardized tinctures.

It may seem at first to some that there is no need in that case of having a standard at all. Not so, for it is impracticable to make standard galenical preparations from drugs containing less than a certain proportion of active principle. The preparation would be greatly overloaded with inert matter.

In the case of drugs that are occasionally prescribed in substance, the pharmacopeia should, as in the case of opium again, provide a standardized powder, adjusted accurately to a fixed definite strength. The ordinary retail pharmacist, of course, could not supply such a powder. Only large manufacturers or dealers could afford the necessary expense and labor involved in making such adjustment of strength, which could only be effected by mixing in the requisite proportions drug below with drug above the required strength, or by the use of a suitable diluent such as sugar of milk.

The problem how to compel the retail druggist to furnish only standard powders in filling the physicians' prescriptions is one that immediately presents itself. Unless physicians understand the matter thoroughly and are in earnest in insisting upon the use only of standardized preparations in filling their prescriptions, the pharmacopeia will remain in this particular a dead letter. Do not understand me to say that physicians themselves will have to do the necessary police work to

secure this end. All that they need do is to post themselves to begin with on the requirements of the new pharmacopeia, and then let the druggists know that they *must have* only the standard drugs and preparations of the pharmacopeia dispensed in filling their prescriptions. The enterprise of manufacturing houses that are keenly competing for the druggists' patronage will do the rest, even without recourse to legal enactments. It is apathy on the part of physicians with regard to matters pertaining to pharmacy that generates in the pharmacist apathy with regard to his professional obligations, which include scrupulous adherence to the requirements of the pharmacopeia.

The practical questions which just now vitally interest the physician are those of the actual standards to be fixed in the new pharmacopeia. The settling of these questions we can not afford to leave wholly in the hands of mere pharmacists. We understand better than they do the importance of conservatism with regard to changes in the character of pharmacopeial preparations. We know very well that more than 50 per cent. of the prescribers in our country—I purposely put the figure low—will not know anything about any changes that may be made in the pharmacopeia of 1900. They will write "Tinet. opii" or "Fl. Ext. nucis vom." as they have been in the habit of writing it, assuming, if they know at all that there is a new pharmacopeia, that there has been no material change in the strength of those preparations. Certainly 25 per cent. of the druggists, to put the figure again a low one, will continue to use the official galenical preparations made in accordance with the pharmacopeia of 1890—or 1870 perhaps—either on the assumption that no material change can have been made in the formulas, or else with the certainty that the physicians who prescribe them expect to get what they have always had under the official names in question.

On the other hand, there is a class of pharmacists to whom changes in pharmacopeial formulas, made with reference to some ideal of uniformity from the pharmacist's standpoint, seem a matter of small consequence. From such men comes the recommendation, for example, that all the tinctures of the new pharmacopeia be made in the proportion of one part of the drug in five fluid parts of the product.

How, then, shall we determine the new standards? We of the pharmacopeial revision committee desire to get an authoritative expression on this question from a representative body of physicians, such as this one. My own view is that the aim should be to make the new standardized tincture as nearly as possible identical in activity with the tincture prepared by the present official method from drug of average good quality.

In the case of tinctures, indeed, I incline to favor the plan that has been adopted in the British pharmacopeia, of making the various tinctures of such strength that the ordinary dose would be in each case a certain quantity. The British pharmacopeia makes two classes of tinctures; in one the ordinary full dose is a teaspoonful, in the other it is 15 minims. This seems to me confusing. If there is to be posological uniformity at all, it ought to be absolute uniformity, otherwise mistakes would be even more liable to occur than were there no pretense of uniformity. As a matter of fact, our present tinctures, with very few exceptions, might be included in one class or the other, of those of the British pharmacopeia. My suggestion has been to eliminate altogether the exceptional tinctures, such as those of aconite and veratrum viride, and in some way distinguish in the

nomenclature the "potent" from the "normal" tinctures, the latter those having a teaspoonful dose.

Except as slight changes in strength may seem to secure more perfectly uniformity of dose in preparations having the same generic name, my view is that the new standards should aim to leave official preparations as nearly as possible of their present strength.

An important case, and one that demands special consideration, is that of the tincture of opium. The strength of this much used tincture has undergone important changes in the past. Thirty years ago it was made of such strength that thirteen minims (more exactly 13.2) represented one grain of opium, supposed to contain 10 per cent. morphin. In the revision of 1880 the strength of the opium used was raised to 12 to 16 per cent., and one grain of this opium was to be contained in about 11 minims (10 grains) of the tincture. In 1890 the strength of the opium was restricted to 13 to 15 per cent. morphin, and now 10.5 minims of the tincture were to represent one grain of opium.

Soon after the pharmacopeia of 1880 was issued some of the prominent manufacturers adopted as a standard for tincture of opium, six grains of morphin (hydrated) to the fluid ounce, which was about the average according to official requirements. The same standard continued to be used by manufacturers under the pharmacopeia of 1890, although very near the minimum requirement. For twenty years, therefore, the tincture of opium has been maintained by the influential manufacturing houses at a uniform fixed standard, and a very large part of the tincture now used in this country is thus standardized.

It is now proposed in the coming revision of the pharmacopeia to make the standard for powdered opium 14 to 14.5 per cent. hydrated morphin and maintain at the same time the ratio of 1 to 10 between powdered opium and the tincture. This means an increase in the strength of tincture of opium amounting to from 5 to 10 per cent. Is this advisable or even justifiable?

Consider in the first place the fact that our tincture of opium is already much stronger than the corresponding preparations of the British or the German pharmacopeias. If any change at all were to be made, it seems to me that it should be in the opposite direction. The present standard of 1.325 per cent. of morphin, or 7½ grains morphin sulphate (equivalent) to the fluid ounce, is certainly not a convenient one. An increase in strength such as that proposed would enable us to set the standard at the very convenient figure of 8 grains morphin sulphate (equivalent) to the fluid ounce, or one grain to the fluidram. This certainly would facilitate calculations, and possibly this consideration in the minds of some would outweigh the objection that it involves a change of about 6 per cent. in the strength of one of the most important of our medicaments.

Personally, I favor retention for the present at least of the standard to which we have become accustomed, since it is so widely accepted by manufacturing pharmacists. If a change is thought admissible, it should certainly be, as I have already said, in the direction of bringing our pharmacopeia more nearly in accord with those of other countries. A change even in this direction of as much as 10 per cent. in the strength, I do not think would be advisable. It would require fully as great a change as this to meet the German pharmacopeia half way. The discrepancy between our tincture and that used by our neighbors on the north is so great that compromise is quite out of the question. A return to the standard in use previous to 1880 would put us fairly

in harmony with them, but such a change can hardly be advised. It is not greater, indeed, than that made in the revision of 1880, but at that time exact standards had not come into general use.

If we reduce the strength of the tincture from 1.325 to 1.25\* per cent. morphin, it is perhaps all that we can do at present towards bringing our pharmacopeia into agreement with those of other countries. One fluid ounce of the tincture, in that case, would contain the equivalent of very nearly 7 grains of morphin sulphate, 8.4 minims, instead of 8 minims as at present, containing  $\frac{1}{8}$  grain of the morphin salt.

The following table shows the comparative strength of the tinctures in question:

|                         | Grains<br>opium<br>to<br>fl. oz. | Per cent.<br>morphin<br>(hydrated)<br>in opium. | Grains<br>morphin<br>to fl. oz. | Grains<br>morphin<br>sulphate<br>to fl. oz. | Number<br>of minims<br>= $\frac{1}{2}$ gr.<br>morphin<br>sulphate. |
|-------------------------|----------------------------------|---|---------------------------------|---|--|

I have said enough to indicate the nature of the problems which are engaging the attention of the revision committee, and I hope that I have brought home to you as physicians your individual and collective responsibility in relation to the solution of these problems. If I have in any measure succeeded in this, the object of this paper has been accomplished.

#### DISCUSSION.

PROF. C. S. N. HALLBERG, Chicago, said that standardization of crude drugs, if not the burning question, is at least one of those now before the Committee on Revision of the Pharmacopeia. Until the seventh decennial revision, that is to say previous to the revision of 1890, there was no normal standard fixed for any drug, except for opium, for which there was a minimum of 10 per cent. of morphin established. The Pharmacopeia of 1890 required that dry powdered opium should not contain less than 12 nor more than 16 per cent. of morphin; rather a wide range when its therapeutic applications are considered. In the decennium of 1880-90, there had been a great deal of work performed, especially by Dr. Lyons and others, upon alkaloidal assays, and it was thought that the principle of fixation of alkaloidal strength of drugs would be quite largely applied in the revision of 1890. But it was found, by the time the Convention assembled in Washington, that the progress that had been made had not been so great as to warrant the application of this principle to more than three drugs, opium, cinchona and nux vomica, and to the preparations of opium and nux vomica, but not to the preparations of cinchona. Since then, the work has gone on apace, especially among the Germans, but also in this country. In laboratories of Philadelphia, and the University of Michigan at Ann Arbor, particularly, processes have been formulated which would be applicable to drugs for analysis; but whether these processes can be extended to every drug and alkaloid, or active principle of glucosidal character, is another question. He was inclined to believe that as long as studies in the constitution of drugs are still incomplete (the active principle of aconite, for example, has not been accurately determined at the present time, and digitalis and other drugs of like character are still unsettled as to the character or identity of their active constituents), it would be a pretty difficult problem to attempt to fix any definite value to these drugs in the Pharmacopeia. He did not, therefore, believe that this principle of standardization could be extended to many more

drugs than has already been done, or carried out except in a very limited way. He believed that physicians should have some guarantee that the preparations they are using, such as digitalis and ergot, should have at least the minimum of what has been determined to be the active principle. It is due to physicians that this much of the principle of standardization should be preserved; but to lay down definitely the exact proportion of the principal constituents of each drug is a little too much to require. We have not yet reached the stage when that can be done with safety. There are so many men on the Revision Committee who understand the needs of the profession in this respect, that the speaker had no doubt that it will be carefully considered and the principle applied as far as compatible with safety.

F. J. WULLING, Minneapolis, Chairman of Delegates from the American Pharmaceutical Association, expressed his hearty concurrence with what had been stated in the paper and by the preceding speaker. He believed that a representative body like this Section could exert much influence in bringing about a condition of affairs so desirable as the standardization of the crude drugs and preparations of the Pharmacopeia. Druggists have knowledge of the different varieties and varying qualities of drugs in the market, and with the exception of what has been done by the Pharmacopeia, they have no methods of determining the value of these drugs. At the present time, there is no sure way for the physician to determine the value of the drug or preparation which he orders, that is to say, of determining the active constituents, and their proportion so as to base his dosage upon that fact. The speaker agreed with Prof. Hallberg that we have no process of analysis, at present, to determine the active principle of digitalis; unfortunately as soon as one is formulated, someone else immediately shows that it is unreliable and that it varies in its results. While there are many difficulties in the way, still he felt that progress has been made in applying the principle of standardization; and he hoped to see it extended further. For example, he had recently had a specimen of belladonna shown to him, which appeared to be a first-class specimen of the drug. He used it to make a tincture, and found upon dispensing it that physicians reported that they could get no therapeutic effect from it. He tested it upon a dog and obtained no result at all. Further investigation proved that the drug was inert; it contained no atropin. It was a handsome specimen in appearance, but it contained absolutely no active principle. At the present day, the druggist must depend largely upon the physical appearance of drugs unless the tests are given in the Pharmacopeia. The careful pharmacist tests every tincture to see what effect it has and to satisfy himself that there is some virtue in the drugs, not in a very scientific way perhaps, but still it does test their value. We have at present some methods of standardizing crude drugs, and the speaker believed it advisable to adopt these processes in the next revision, and make others as they arise. We can not do all that we desire at once, but we can make a beginning. Dr. Lyons had stated his belief that the ordinary druggist does not have the appliances for carrying out the processes recommended by the Pharmacopeia. The speaker believed that, from personal observation, he would be safe in saying that about 10 per cent. of the pharmacists have the proper appliances to make such analyses, according to the processes recommended in the Pharmacopeia; and he thought that the other 90 per cent. would do well to supply themselves from prominent houses that make standardized preparations. But it does not rest entirely with the pharmacists. Physicians should interest themselves in this subject far more than they do. They should acquaint themselves with the requirements of the Pharmacopeia and insist upon having official preparations. If they do insist, the druggists will only be too glad to supply them. We know that physicians of late years have not confined themselves to the official preparations, but prescribe a number of commercial preparations not in the Pharmacopeia. Possibly, this may be largely due to the greater convenience of ready-made pharmaceuticals. Some years ago, he had taken occasion to interview a number of physicians to solicit their

\* 1.25 grams in 100 c.c. of the tincture.

support for the "National Formulary" and he was quite successful in obtaining their help. Physicians told him that they wished their drugs to be reliable, and if they specified the manufacturer, it was in order to obtain a good article; if they felt assured that they could always get a reliable tincture or fluid extract, they would prescribe them in preference to the proprietary preparations. Attention of physicians should be drawn to the "National Formulary" of the American Pharmaceutical Association, because it contains formulas especially prepared to relieve physicians of the necessity of prescribing secret proprietary preparations which are not compatible with the dignity of physicians and which they prefer not to use. Some physicians hesitate about writing extemporaneous prescriptions on account of incompatibility and of making unpleasant combinations. They find it more convenient to order pills already made, and save themselves trouble. The speaker urged that the members of the Section use their influence to have the medical colleges of this country introduce the Pharmacopeia as a text-book. As it is, many physicians have never seen a copy of the Pharmacopeia and do not know it from the Dispensatory. He thought that most of our colleges pay very little attention to pharmacy, which is a great mistake. If practical pharmacy and materia medica were made more prominent in the curriculum of the medical colleges, he thought that the new graduate would be better qualified to practice his profession. He had met physicians who had never seen iodid of potassium! One physician told him that he did not know whether paregoric contained any opium or not! Where there is power, as there is in this Association, if it be used judiciously, much can be accomplished. With regard to standardization, he thought that it should be accomplished as far as possible at once or without unnecessary delay.

Dr. A. M. WILSON, Kansas City, said that some years ago a class of men about to graduate from a medical school, about fifty in number, came to him for private instruction, and he found that not one of them could tell the difference between a tincture and a fluid extract. Although not practicing pharmacy for several years, he still has a private laboratory and is much interested as a graduate in pharmacy in the subject under discussion. We all know that a prescription, say for tincture of belladonna, taken to a half dozen different druggists would very probably bring back a different preparation from each one. He was, therefore, in favor of standardization. He advocated a better understanding between physicians and druggists, and thought that it would be better if the medical graduate could be made more of a druggist than he is at present. While the foundation of medicine is diagnosis and pathology, the superstructure is pharmacology and therapeutics. The text-books, however, are devoted almost entirely to pathology and say very little about the administration of drugs. He was certain that no satisfactory understanding can be reached until the physician knows as much as the druggist. At present, the Pharmacopeia is a sealed book to the physician and the average student coming out from a medical school is not competent to prescribe drugs, and therefore may easily be led off into Eddyism or other vagary. Out of a class of 122 that went out from a Kansas City medical school, there was only a very few who knew anything about the Pharmacopeia or the preparation of drugs. We should realize the tremendous responsibility of this subject and endeavor to have pharmacology more thoroughly taught. He believed in the use of standard drugs upon the standard human being, and he hoped that the effort to secure uniformity would succeed for the happiness of posterity and reputation of the medical profession.

Dr. W. L. DICKERSON, St. Louis, Mo., said that with reference to the criticism that medical students go out without any knowledge of materia medica, he thought that it could not be any different under the present arrangement of studies. The student taking a four-years' course is expected to complete his studies of materia medica and pharmacy in the first year. He said that it would be better if these studies were made continuous throughout the four-years' course. He was glad that the revision of the Pharmacopeia was in the hands

of authorities who are giving due attention to the subject of standardization. The strength and dosage of tinctures are very variable and he thought that there could be no uniformity as long as the strength of tinctures varied all the way from 5 to 35 per cent.

Dr. N. S. DAVIS, JR. (Chairman), said that he had for a number of years given much thought to the subject and he approved of the adoption of standardization of drugs and preparations just as soon and as far as possible. At present, however, the field in which it can be done with safety is very restricted. As a member of the Revision Committee, he had endeavored to carry out one plan, which he had always desired, and that was to make the Pharmacopeia more useful to medical men. He thought that physicians should be interested in it just as much as druggists are; it is the common standard for the two professions. It has not, hitherto, been arranged for physicians, but for druggists, and is not especially interesting to medical men, although it might be made a useful work in reference for both. With regard to instruction in medical schools, medical students in their first year acquire a certain amount of information with regard to materia medica and pharmacy, just as they do of physiology, information which they afterwards make use of during the remainder of their course at college. It can not be said with propriety that these studies are discontinued at the end of the first year, because they constantly make use of them throughout the entire four-years' course. He thought it very necessary in order to obtain definite results from drugs, to use products which are standardized, in preference to allowing the prescriptions to be filled with unreliable preparations which would not yield uniform results. Returning to the Pharmacopeia, he said that, in his opinion, all the new remedies should be placed therein, in order that physicians might be able to consult the Pharmacopeia for the latest authoritative information about drugs. It should not be a volume of standards, nor attempt to say with authority what drugs should be used, but a reference book. It should, therefore, contain all the newer drugs, whether they had been tested or not: these possibly might be put in an appendix, but all the new ones as well as the older preparations should be contained in it; the latter because they are still used by some physicians. As regards teaching of materia medica in the leading medical schools at the present time, laboratory courses are given in pharmacy, where the students are made familiar with the appearance of crude drugs, their chemical tests, and how to make the preparations. This course is supplemented by one on the physiologic effects of drugs. As students so taught come out and enter the profession, he felt sure that they will be far better informed as to the effects of drugs than those who graduated some years ago, of the class to which the last speaker had referred. It can not be said that these subjects do not receive sufficient consideration in our principal medical schools.

## THE PROPER MANAGEMENT OF THE TUBERCULOUS LUNG.\*

NORMAN BRIDGE, A.M., M.D.

LOS ANGELES, CAL.

How to manage a lung infected with tuberculosis so as to give it the best possible chance of recovery is a great desideratum, and only second in importance to the general management of the system as a whole.

A better understanding of the normal process of recovery of tuberculosis and of diseased lung tissue in general, makes it necessary for us to revise our notions of the proper hygiene and management of the tuberculous lung. It is necessary that we should recast our theories of cure and change our procedures with the lungs themselves. We must learn new ways, or rather

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee. Drs. Thomas Hunt Stucky, Leon L. Solomon and N. S. Davis, Jr.

the ways of Nature, as shown by wide observation of disease in other parts of the body and by experience with sick lungs themselves; and we need to reject and relegate to the rubbish pile a lot of doctrines that have been held and followed with the faithfulness of devotees by the public and profession alike. Some of these doctrines originated in the theories of non-professional persons with a superficial knowledge of physiology, and grew out of their reasoning as to what ought to be the truth, and therefore ought to be the procedure. It is an interesting as well as a pathetic fact that the profession has in the past fallen so readily and innocently into the habit of believing and following the theories of the lay public. It is likewise pathetic that we of the profession are wont to continue to rock along in the old ways for decades without stopping to consider whether better ways are possible. Some things by the light of this day must become axioms.

1. Shallow breathing is important and beneficial for a tuberculous lung that has to breathe. Better than that is no breathing. The good rule to put a sick organ at rest finds no exception here. Quiescence gives the forces of Nature the best chance. Put the sick lung part to rest if possible. The effects on the tuberculous lung of serum or gas in the pleural cavity in compressing the organ and so putting it to rest, have almost invariably been good, and they have gone far toward a demonstration of this proposition.

2. Deep breathing, or an occasional deep breath, is often urged as a measure to expand the lungs, which is a thing that has been supposed to be useful in tuberculosis, as well as to favor expectoration. The exit of the products of the disease is vital to prevent the occurrence of fever, and fever or the poison that causes it or both are what, if they last long enough, wear out the life of the patient. Many of us have been, I am convinced, guilty of giving this advice too freely, even recklessly and without pondering the effects of the measure. If it is so vital that phlegm within the tubes shall be expelled promptly a better way is to teach the patient to cough at the end of an expiration, when half the effort will accomplish the purpose; for this maneuver partially collapses or narrows the bronchi (and cavities if there are any) so that phlegm masses are more easily caught by air currents; and makes it possible for a small amount of air on the distal side of such a mass to expel it with great ease, when moving outward and into larger tubes with only a moderate degree of air pressure.

But are we sure pus within the bronchi is so very harmful? Fever is probably produced much less by absorption from within the bronchi than many of us have been ready to think. There is strong reason to believe that highly poisonous phlegm may remain inside the tubes for a long time without doing much harm. The real seat of mischievous absorption is, probably, mostly infected areas outside the walls of the tubes or the substance of the tube walls themselves. The patient suppresses his cough because cough appears to his mind synonymous with sickness; so if he can by any trick resist it he is in his estimation getting well. The doctor is likely to blame him for retaining his phlegm lest its poison shall be absorbed and produce fever; but it is almost certain that the benefit done to his lung by the quiescence of the organ due to suppression of the cough, a great deal more than counterbalances any injury done by absorption from within the bronchi.

3. Quiescence of the lung favors the limitation of the disease by fibrosis around and within the part involved, with the smallest amount of fibrous tissue; and

the smallest amount that can be effective is always desirable. Deep breathing does violence to the fresh, new fibrous tissue and so probably stimulates the further and excessive growth of it, exactly as manipulation of an open sore tends to an increase of scar tissue. Sometimes a patient recovers or is in a fair way to recover from his tuberculosis, to die from the damage due to excessive fibrosis. For, while moderate fibrosis is a conservative process, excess of it may be dangerous by cutting off the blood supply of the parts and so leading to destructive ulceration of lung tissue, dyspnea, debility and death.

4. There is no particular need of or significance in the popular efforts in the real or supposed expansion of the chest by deep breathing and wide movements of the arms. These measures may do well enough for the healthy who fear they may get sick, but never for the victims of pulmonary tuberculosis; and no arm movements or raising or retracting of the shoulders can ever expand a chest anyway, since the shoulders glide over muscular masses around the cone of the chest without changing its diameter or its position. That they can so act is a layman's theory, founded in poor knowledge of anatomy.

5. Altitudes do not help the sick with lung tuberculosis by expanding to a greater degree the air vesicles. The theory is fallacious, unphysiologic and wrong. The benefits of altitude must be explained on the theory of the increased number of the red blood corpuscles even if they are reduced in size, and of attendant and other advantages to the general nutrition of the body. These advantages are not discounted when we try to explain them on the rational ground of known physiologic changes, instead of on supposititious grounds which are founded in error.

6. Breathing through diminutive contrivances of tubes with large inlet and smaller outlet so as to produce increased pressure within the chest to expand the air vesicles, is harmful if any effect at all is produced. At best it only does the thing that every act of coughing produces, and produces with less harm than the steady, long continued pressure in the sustained effort at blowing, that so many people have practiced.

7. The habit of public speaking is distinctly harmful in consumption, doubtless because it increases the motion of the lungs and increases the pressure within them. It has been the practice of many of their physicians to permit clergymen with mild tuberculosis to continue preaching. I am satisfied that it is wrong and that the rule should be with every such patient to stop all public speaking, until at least a year after recovery is complete.

8. Every act of coughing must *ipso facto* increase the pulmonary air pressure and so tend to stretch the air vesicles and disturb the new and soft fibrous tissue and favor absorption into the veins and lymphatics of the lung. So cough should be minified as far as is consistent with free expectoration of the accumulated phlegm, and coughing efforts should be made with as little pressure as possible. Let a patient cough at the end of a profound expiration and he will discover that he can raise his phlegm with a quarter of the air pressure that he would use if he coughed at the end of a deep inspiration, with every bronchus and cavity stretched to its utmost. There is much cough that is useless since it fails to bring up any phlegm whatever. It is a blind automatic effort of the sensitive nerves of the irritated mucous membrane, provoked by some irritation beside that of phlegm that can be expelled. As this tends to injure the air vesicles and increase fibrosis we should en-

deavor to lessen it as far as possible by means not of anodynes administered internally, but perhaps by soothing inhalants, warm clothing and careful attention to the needs of the system as a whole. Anodynes may become necessary occasionally as the lesser of the two evils.

9. Posture of the diseased part is usually forgotten as a factor in either the diagnosis or management of tuberculosis. That in one-sided tuberculosis, cough and wheezing are increased by lying recumbent on one side, and are decreased by reversing the posture, is a valuable aid in diagnosis, and points almost unerringly, if it is early in the progress of the case, to disease on the side that is undermost when the symptoms are excessive. This is due to the influence of gravity on the phlegm. When the substance can flow downward into larger tubes or into the windpipe, râles decrease and there is less tendency to cough. When the flow is distally toward and into tubes decreasing in size râles increase, and cough is produced by contact with healthy bronchial surfaces. Except in the rarest cases, it is only when the disease extends to the very surface of the lung that this symptom is wholly absent.

To keep the sick part uppermost favors the outflow and exit of disease products and so is useful for the part itself. To lie on the well lung therefore lessens useless cough and so far keeps the sick lung quiescent and gives it better opportunity for recovery. But on the other hand it favors the flow into the undermost and well lung, by gravity and suction together, of pus and other fluids, sometimes to the extent of carrying the disease to normal tissues; and this is the greatest misfortune of all. How much any hypostatic congestion of the well lung in this posture may handicap it and predispose its tissues to acquire tuberculosis must be a matter of conjecture, but there can be no question that to keep an uninfected lung in safety is a paramount duty.

It is a common observation that tuberculosis begins in the right apex, and as it recovers there breaks out in the bronchi of the left side, not at the very apex as was the case on the right side, but in the region of the second interspace and where it might be expected to appear if it should be an infection conveyed through the left main bronchus. By reason of the angle of this bronchus with the trachea the erect posture of the body favors the return of phlegm into the left rather than the right side, and this fact may well account for most of the cases of spread of the disease to the left lung in the region named and under the circumstances described. But it is only fair to assume that some of these cases are due to lying on the left side to avoid the coughing and wheezing threatened by a diseased right lung. And it is a serious question how far the patient should indulge himself in posture to escape the discomfort of coughing, when he is thereby in danger of an extension of the disease. I am coming to doubt whether in cases of much phlegm it would not be better to lie on the diseased side most of the time while in bed, turning to the opposite side occasionally to assist in coughing out the phlegm, than to pursue the usual course of keeping the sick side uppermost. It is true that such a procedure favors the flow of fluids distally and into perhaps uninfected small bronchi, but the quiet respiration of sleep would hardly do this, while it might suck phlegm into the large bronchi of the opposite side. Then the uppermost lung in lateral decubitus probably always expands more and does more breathing than the other one, and this is an unfortunate proportion; the major work ought to be done by the well lung.

10. There is now no reason to doubt the great value of immobilization of the diseased lung, especially in those cases where (the lesion being unilateral) one healthy lung remains capable of taking on extra duty. This doctrine has greater force and value in tuberculosis than any other disease.

Gas inflation of the pleural cavity, according to the method of Murphy, is undoubtedly the best way to accomplish this purpose where it can be done. But it is often inapplicable by reason of extensive adhesions preventing the distension of the cavity; by reason of lack of the proper apparatus; of lack of experience or skill on the part of the physician; or of courage on the part of the patient or his friends. It is chiefly adapted to the incipient stage of the disease and before adhesions have taken place; and adhesions develop as a rule rather early in pulmonary tuberculosis. At the same time many of the patients that show most benefit from fixation of the diseased lung, and that most need it, are more advanced cases, that are even more deserving of consideration, if less promising for recovery. External fixation ought to come into vogue for these patients, for it may be applied to nearly all unilateral cases in all stages of the disease, and has the merit of relative harmlessness, ease of application and general adaptability. From it patients often experience great benefit even from the moment of its application.

11. The method consists in fixing the diseased side as far as possible by means of numerous strips of firm adhesive plaster or some other apparatus, as a plaster of Paris splint or one made of some other material. In using the plaster the strips are drawn tightly about the side, ending somewhat beyond the median line of the body and are spread out in divergent lines extending from below the axilla, where they are gathered to avoid discomfort to the patient. Thus applied they do not interfere with the free movement of the well side, while they exercise a firm pressure on the side to be stilled. By this measure the ribs of the side may be considerably restricted in their excursions in respiration, and the lung beneath be likewise restricted in action. The reduction in the lung motion is, of course, less than that of the ribs, since the mediastinum constitutes a partition between the two sides of the chest that is movable to quite a degree by reason of its elasticity, and will always allow the lung we attempt to confine to expand in a measure, by itself stretching over toward the side of greater motion. But the partition, with the weight of the heart and great vessels, exercises some physical force against lateral movements, and that, such as it is, helps the efforts toward fixation of the lung.

Even if one side of the chest wall and the mediastinum were fixed and immovable, still wide excursions of the diaphragm could easily neutralize to a large extent the effects of this condition and allow all parts of the lung, except the very apex, to expand rather freely. The motion thus produced would be greatest at the base of the lung and shade off toward the apex where it would be slight.

The movements of the diaphragm may be minified by voluntarily breathing exclusively with the chest movements. It is possible for one to create a habit of doing this, but the average patient probably never will accomplish it, for he has too little fortitude and continuity in mental attention for so severe a test. And even if it were possible we could not expect the habit to be carried into the hours of slumber, which are quite as important as any other part of the day. But it is unwise and unfair to tax a consumptive with the duty of watching the

manner of his breathing. To be quiet and protect others from his expectoration is about all we ought to ask him to do.

The diaphragm may be to a very large degree immobilized by pinning a firm bandage around the abdomen, and thus abolishing as far as possible abdominal breathing. The bandage should be made of stout and inelastic cloth; should reach from the epigastrium to the pubic bone and extend over the lower ribs above, and the pelvis to near the hip-joints below. It should be drawn as snug as the patient can bear with comfort, and be fastened with safety pins placed not over an inch apart. To prevent it from sliding up and gathering about the waist the ordinary perineal thigh straps may be used.

The strips for the chest wall should be a good article of rubber adhesive plaster, or some other adhesive material, two inches wide. They should be drawn firmly and applied with the chest erect and in the state of extreme expiration; they should be numerous enough to cover the whole side, should overlap freely, and be sure to extend some three or four inches beyond the median line both front and back.

In applying the strips it is important to avoid placing them so that they will cut under the arm. If the arm is in the position of extreme elevation when the uppermost horizontal strip is applied it will almost certainly be placed too high and hurt the skin when the arm is brought down and carried in that position. The best way to apply this one, as for that matter all of them, is with the arm hanging by the side, the plaster being first carried under the arm and applied to the axillary line at the proper height, after which the ends may be stretched into place with the patient in full expiration. Then a number of strips should be applied diagonally in such a way as to avoid the axillary region. The strip that begins over the epigastrium ends at the inner end of the spine of the scapula on the well side; and the one that begins at the upper point of the sternum ends below the scapula of the well side. Thus the strips in the upper part spread out like a fan both front and back, while the lower ones are nearly or quite horizontal. The best rule as to the sequence of application of the strips is to fix the lowest horizontal one first, then the next above and so on, the diagonal ones at the top coming last. The patient should expire freely as the ends of each strip are drawn to place. Finally two strips of plaster superimposed should be drawn firmly over the shoulder, between the acromion and the neck, and extend down front and back lower than the horizontal strips and pressed firmly against all of these. These pieces tend to fix the upper ribs and give comfort to the chest. It is better not to have them stick to the shoulder. This may be prevented by first placing over the latter two layers of soft cloth extending to the diagonal strips of plaster. When well and fully applied the side of the chest is almost completely covered by the plaster.

The plaster dressing should, when once well applied, be allowed to remain unmolested as long as it serves the purpose of fixing the chest wall, or until it becomes annoying to the patient by producing some irritation of the skin. Then it may be taken off and the skin be washed with alcohol or dusted freely with bismuth, or some skin dusting powder, to remove any particles of plaster, when, if conditions are favorable, it should be reapplied as before. This round of measures should be repeated as many times successively as the case requires.

The skin is sometimes irritated considerably by the plaster, and pimples and slight excoriations occur. But

these usually recover in a day or two when the plaster is removed; then it can be reapplied. The skin irritation is useful to the lung and intercostal tissues rather than otherwise; moreover, the skin often seems to become after a while toughened or accustomed to the plaster, so that this ceases to irritate.

The greatest difficulty is in the tendency of the plaster to creep or slide, and as soon as it becomes so slack as to cease to keep the chest considerably immobilized it should be removed at once, and be reapplied as soon as possible. A surgical appliance much needed is a plaster that is highly adhesive and that once applied will not creep at all; but perhaps these conditions are impossible.

An interesting effect of the strapping, discoverable after it has been maintained for many days, is a restriction of motion in the affected side after the adhesive strips are removed. By idleness the respiratory muscles of this side acquire the habit of rest; and by increased duty those of the opposite side take on a habit of larger activity.

The abdominal bandage does no harm in any way except by depriving the abdominal organs of their accustomed gentle and natural massage due to the habitual movements of them that are produced by abdominal breathing. But this lack can easily be compensated for by removing the bandage occasionally and freely manipulating the abdomen. The bandage does not need to be so tight as to interfere with the circulation or press downward harmfully the pelvic organs, as tight lacing so often does. The purpose is solely to stop abdominal breathing as far as possible or as far as is consistent with good digestion and elimination; and abdominal breathing may usually be almost or quite abolished without interfering seriously with these functions.

The effect of this measure for immobilization of the chest will be found, in many cases, to be highly beneficial; in some cases the instant comfort experienced by the patient is a striking feature even where no chest pains have existed previously. The comfort comes from a quieting of the noises in the chest and from a feeling of rest. In substantially no case is it harmful, provided there is one healthy lung to be used; and it is borne without special discomfort by a large proportion of patients. A catalogue of the good effects includes: 1, considerable relief from useless cough; 2, increased ease in expectorating; 3, relief from the annoyance of râles and wheezings, which tantalize some patients into desperate insomnia if not into the grave; 4, relief of pain in the chest walls; 5, relief from a sense of fatigue in the chest which so many patients have; 6, lessening of fever, and consequently improvement in general nutrition and tone; 7, lessening of danger of hemorrhage and assistance in recovery from its effects; 8, aid in the healing of cavities, especially small ones; 9, decrease in the amount of fibrosis beyond what is necessary for a conservative force. There can be no question that immobilization in this way is a sustained benefit to the process of recovery; and I do not know of any other harmless measure that gives so much comfort to the average patient, except the inflation of the pleural cavity with gas.

But these good effects in tuberculosis do not comprise all the advantages that are sure to accrue from the faithful use of this measure. It has been used for the pains of pleuritis for many years; it is just as proper for intercostal neuralgia and for pleurodynia, as for any other pain in the chest that is produced by the motion of respiration. It may be used with benefit for empyema after drainage has been established; it will help toward the collapse of the cavity and early healing with a minimum

of fibrous tissue, and thus with more final use of the lung. It ought also in such cases to lessen the danger of amyloid degeneration of important organs from prolonged suppuration. It ought to be tried faithfully in bronchiectasis confined to one lung, in the hope of lessening the amount of fibrous tissue produced by the disease and so making the havoc to the lung and general system less.

### THE NATURE AND HISTO-PATHOLOGY OF THE EPIPHARYNGEAL TONSIL.

NORVAL H. PIERCE, M.D.  
CHICAGO.

The body which is known as the third, pharyngeal, or better, epipharyngeal tonsil, and when hyperplastic, as adenoids, is situated at the superior part of the posterior wall of the epipharyngeal space, and constitutes the upper portion of Waldeyer's ring, the median and lower portions of which are completed respectively by the faucial and lingual tonsils, the whole being connected by a system of delicate lymphatic vessels and nodes.

While the honor of first disclosing the local and re-

solitary follicles and Peyer's patches in the intestinal walls. Henle called it conglobular; Koelliker, cytogenous; His, lymphoid tissue. Woake's idea as to adenoids being of a papillomatous nature has long since been proven erroneous. Indeed, this adenoid tissue is widely distributed throughout the body. It is abundant in the pharynx; in the esophagus it is almost absent, and in the stomach inconstant; but it abounds in the intestinal canal, especially in the ileo-cecal region, while in the rectum and about the anus it again becomes scant or altogether absent. It is found in the conjunctiva, in the tear ducts and in the mucosa of the female genitals. The trachea is rather free from the adenoid structure; but in the larynx it is constant, and is most frequently abundant in the ventricles and the interarytenoid region, on the free edge of the epiglottis, on the petiolus, in the aryepiglottic folds and in the sinus pyriformis.

Knowledge of the distribution of adenoid tissue in the postnasal space and adjacent structures is of practical

Figure 1.

Showing size and position of a normal epipharyngeal tonsil.

Figure 2.

Showing adenoid tissue embracing Rosenmüller's Groove.

remote significance of adenoids belongs to Wilhelm Meyer, first in 1868, then in 1873, their existence can hardly be said to have been altogether unknown to the ancient writers. Although he was ignorant of the real cause, Hippocrates, in the 7th Book of Epidemics, gives the clinical picture of adenoids with the concomitant ear discharge, headache, irregularity of the teeth, V-shaped palate, etc. We may gather from Celsus that the effects of adenoids were not unknown to him. Pliny mentions them. Semon draws attention to a picture of a Prince of Spain painted in 1524, in which the artist has portrayed the facies peculiar to those affected with mouth breathing. Schneider (1655), Santorini (1724), Haller (1764), Lacauchie (1853), and Luschka (1868) more or less perfectly described the morphology of the epipharyngeal body, and it was the latter investigator who first conferred on it the name, since generally accepted, the tonsilla pharyngea. Henle, Koelliker and His were the first to examine its histological structure, and to show the histological similarity existing between this and other remote lymphoid structures, namely, the spleen, the thymus, lymph glands,

import, inasmuch as the whole or any part of it is liable to undergo hyperplastic change.

The normal pharyngeal tonsil may be said to occupy the space reaching laterally from one Eustachian cushion to the other, and from the superior margin of the choanæ above, to the arcus atlantis below. It is flat and traversed by three to five or more vertical grooves, which tend to converge at its lower end; several fissures are usually found running from side to side, intersecting the former. It measures from 4 to 6 mm. in thickness. From here the adenoid tissue reaches over the soft palate into the middle meatus of the nose and along the floor, where it may be often detected by anterior rhinoscopy as a linear projection of pale pink color (Shäffer, Winckler, Hellman). The accumulation is so great on the median walls of the postnasal space and at the ostium of the Eustachian tube that Tentleben suggests that it be called the tubal tonsil. It enters the walls of the tube itself as far as its upper third. Trautman contended that adenoid vegetations never have their origin in Rosenmueller's groove in the im-

mediate neighborhood of the tubal ostium, while B. Fränkel, Schäffer and others have contended that such origin is frequently found. Reference to Fig. 2 shows growth growing directly from the aforesaid region.

Embryologically the pharyngeal contents are associated by means of Landzert's canal with the pituitary body and pineal gland. But as far as I have been able to ascertain the exact relationship of the tonsilla with the hypophysis is not known. According to Stohr the metamorphosis of leucocytes into the fibrillar structure of adenoid tissue begins in the third month of fetal life. In the sixth month the pharyngeal tonsil is formed. At birth, however, a pharyngeal tonsil is very rudimentary, scarcely visible to the naked eye in most cases. Only exceptionally do we find its hyperplastic enlargement beginning before the end of the first year. In the majority of children from the 5th year to puberty the accretion is at its height. From this time on, its tendency is toward involution. In individual instances we have the most varied exceptions to the rule. Thus we may have large masses of adenoids remaining after puberty and into adult life, or we may see voluminous masses undergoing rapid spontaneous disappearance at any age

widely distributed through the animal kingdom by Schmidt, Killian and Holl. It is constant in mammalia, with the exception of rodents, where it is very scant or altogether absent. In swine lymphatic tissue in the pharynx is especially abundant. A lymphatic body analogous to the faucial tonsil as it occurs in man is to be found in birds and in certain reptiles and amphibians.

As to the function of the pharyngeal tonsil little or nothing is known, as little as is known of the part played by the faucial tonsil. Numerous hypotheses have been advanced regarding both, but as yet none of them have been proven. Harrison Allen, reasoning from their embryological connection with the hypophysis cerebri, believed that adenoid vegetations were intimately connected with the metabolic processes of the economy; he says: "I remain of the opinion that adenoid growths, while, as a rule acting mechanically, will occasionally manifest the symptoms of a veritable disease which is allied to other affections of the blood vessels, glands and lymph systems, and which should be regarded as having a dominating influence on metabolic processes. It is thus placed in alliance with acromegaly and

Figure 3.

Showing ripening of embryonal into adult connective tissue in an epipharyngeal tonsil removed from a lad at puberty.

before puberty. We must remember, however, that it does not require large masses of adenoid tissue in infants to greatly interfere with nasal respiration.

The size, shape, color, and consistency of the hyperplastic pharyngeal tonsil vary greatly. Its size may cause it to completely or incompletely fill the postnasal space. Meyer divided them as to shape into folious, conical, pectinate and lamelliform varieties. The archtypal form is that with a broad base, sharply defined, of rather hard consistency, hemispherical in shape and with more or less deep sagittal and transverse furrows crossing its surface. The other varieties may be regarded as the result of modification in corrugation due to anomalies in the normal sagittal and transverse furrows. The color may be pale pink, red or purple. Density varies according to the relative amount of lymphoid and connective tissue a growth may contain, and to a certain extent with its vascularity. The surface may be coarsely granular or smooth. There is little doubt but that they possess a certain degree of erectility.

This peculiar arrangement of the pharyngeal lymphatic system is not limited to man. It has been found

Figure 4.

Blood vessels at the base of a hyperplastic epipharyngeal tonsil, showing their radial arrangement. At *a* and *b* are shown how the fibrous tissue prevents the collapse of the blood vessels.

myxedema." The pharyngeal adenoid ring has been identified with the digestive or absorbent process on account of its histological resemblance to the adenoid structures in the intestinal walls. But the position of the epipharyngeal tonsil would seem to preclude its participation in such a process. On account of its resemblance to the structures which in fetal life are actively employed in the production of hematogenous elements, namely the spleen, thymus, liver, certain observers have endeavored to connect it with the hematopoietic process. Analogy is not born out when we remember that after birth when these organs have ceased their hematopoietic functions, the adenoid structures of the pharynx in the large majority of cases just begin to appear. Again, their great variability would militate against their participation in such an important process. Against the theory that they protect the organisms against infection we have only to recall the frequency with which they serve as portals of entry for diphtheria, scarlet fever, rheumatism, etc.

Hyperplasia of the pharyngeal tonsil has been ascribed to various pathological processes by numerous writers.

Michael Dansac divides them into those of tubercular, syphilitic and scrofulous origin, and bases his deductions on a histological study of 32 cases of adenoids occurring in the clinic of Gougenheim at Lariboisieri Hospital.

The relationship of tuberculosis to adenoids has furnished a theme for discussion by many writers during the last few years, and we are now in position to say that although the epipharyngeal tonsil may not infrequently be infected by the specific germ, its hyperplasia is far more often due to other causes and may be seen by the following table:

|              | 100 cases found | 0 cases of tuberculosis: |
|--------------|-----------------|--------------------------|
| Broca in     | 33              | 4                        |
| Gottstein in | 32              | 2                        |
| Lemoyez in   | 64              | 8                        |
| Brundel in   | 32              | 5                        |
| Plundar in   | 50              | 2                        |
| Luzzatti in  | 78              | 5                        |

| Wex in       |                 |                          |
| Total ....   | 599             | 33                       |

Pillet found giant cells in three cases out of ten specimens examined, but we know that giant cells alone

Figure 5.

Lymph follicles with their more deeply stained peripheries.

found under conditions such as those present in his cases are not evidence of tuberculosis. The reaction of adenoids to the tuberculin test has been negative in the large majority of cases.

In one of G. Gottstein's cases, from which the adenoids were removed, evidences of tuberculosis were found. At the time of removal the patient was 12 years old. Six years afterwards she was again examined. Only the slightest remnant of adenoid tissue remained, which had a perfectly normal appearance and the patient herself was in possession of perfect health.

That we often find adenoids in strong healthy children, must disprove the hypothesis that they are always of tubercular, scrofulous or syphilitic origin. Causes of hyperplasia occurring in the pharyngeal tonsil are various. Among the most frequent stand the acute infectious diseases of childhood; especially provocative are scarlet fever, diphtheria, measles and whooping cough, and next to these come recurrent attacks of acute catarrhal inflammation and acute lacunar inflammation. The frequency with which these attacks occur in the epipharyngeal tonsil has been scarcely appreciated, as pointed out by Gradle.

Whether the systemic disturbances which accompany

adenoids, anemia, aprosexia, etc., are in all cases due solely to their mechanical presence is scarcely probable. The recent experiments of Massini and Genta seem to prove that adenoid tissue occurring in the postnasal space possesses a secretion which when injected into rabbits causes a slowing of the pulse rate and a rise in the vascular pressure, thus placing by analogy adenoids among the glands having an internal secretion, such as the thyroid, adrenal bodies, pituitary gland, etc.

Their coincident appearance in many cases of scrofulosis is admitted. But we are all aware that in certain cases in which the general condition can scarcely be differentiated from true scrofulosis, immediately on removal of the growth in the postnasal space the vital capacity of the individual improves and the patient in a short time is restored to full health. This condition has been called by Moritz Schmidt, pseudo-scrofulosis.

#### HISTOLOGY.

Bickel proposes to confer the name of tonsil on only those masses of adenoid tissue which meet the following specifications: 1, a sharply-defined base; 2, diffused

Figure 6.

Acinous glands from the deeper portions of an epipharyngeal tonsil.

infiltrations of leucocytes around lymph follicles; 3, crypts and sinuses; 4, the lymphatic tissue must approach close to the surface and contain acinous glands.

The epipharyngeal tonsil possesses all of these characteristics. It is covered with epithelium, the character of which varies with the age and size of the growth: in the normal young tonsil it is rather constantly cylindrical and possessed of cilia. In the older growths, however, this cylindrical epithelium assumes more often a pavement-shaped variety and the cilia are lost. The epithelium is arranged in rows of two in the young tonsil; in the older tonsil they may increase to three or five. Immediately beneath is the limiting membrane, which as a rule is very delicate. Below this comes the substantia propria consisting of the lymph follicles, leucocytes, blood vessels and lymphatics, the whole being held together by a reticulum of connective tissue. In a number of sections stained with the fer-hematoxylin method I was unable to find a nervous structure. The size and number of the follicles in any growth vary greatly. The follicles may be so large as to be visible to the unaided eye in the stained section; there may be two to five layers from the surface to base. Nearly always the periphery of the follicles stain more intensely

than the central portion. Deep within the tissues are found the acinous glands. The arrangement of the blood vessels is somewhat fan-shaped. J. Hynitzsch has observed villous elevations within the crypts which show a great similarity to the papillomatous proliferation seen in mammary and ovarian cysto-adenoma. The same author has made a study of the cysts occurring in the hyperplastic pharyngeal tonsil and divides them into two varieties corresponding to the two types of epithelium lining the crypts, namely, the columnar and squamous cysts. These columnar epithelial cysts vary in size from a microscopic body to that of a bean, occur frequently and contain a clear ropy mucus, often rich in leucocytes and occasionally red blood corpuscles. In two cases the cysts contained multinuclear elements or giant cells. Their nuclei vary in number, are of irregular arrangement and never situated along the line of the cell, thus essentially differentiating them from giant cells found in tuberculosis. Squamous epithelial cysts are much rarer. These cysts frequently contain horny lamellæ concentrically arranged, the center composed of amorphous granular masses, fat globules and cholesterol crystals. They may be regarded in all instances as due to retention of secretion by closure of the mouths of crypts. The process of involution may be explained as follows: Maturing of the embryonal tissue takes place first in the oldest portion of the growth, which is probably at the base of the tonsil. This process, together with the peculiar fan-shaped arrangement of the blood vessels may be seen in Figure 4, and here, too, we may gain a hint as to the cause of hyperplasia in certain growths. The firm connective tissue in which the blood vessels of the base are embedded prevents diminution of their caliber and this interferes with the normal decrease in the nourishment of other portions of the growth. We thus have a relatively increased blood supply to that portion of the growth supplied by the blood vessels affected. The change of embryonal into adult connective tissue takes place in the interfollicular tissue. Each follicle is enclosed in a bag, as it were, of maturing connective tissue; this gradually contracting tends to cause the follicles to disappear by pressure atrophy.

#### CONCLUSIONS.

1. The tissue composing adenoids has a wide distribution throughout the body.
2. The epipharyngeal tonsil is an organ normally present in all individuals.
3. The function of the epipharyngeal tonsil is at present unknown. Whether it is simply an evolutionary vestige or has to do with metabolic or other processes is equally uncertain.
4. Its wide distribution among the various members of the animal kingdom, its embryological connections, and its identity with lymphoid structures elsewhere in the body, would suggest that the epipharyngeal tonsil has a function.
5. The histology and the experiments of Massini and Genta would tend to place it in the class of glands having an internal secretion.
6. The relation of tuberculosis, syphilis or scrofulosis to adenoids is not etiologic. Adenoids may be affected with tuberculosis, etc., but only as any other organ may be similarly affected.

**Important Scientific Post for a Woman.**—Since Nencki's death, his assistant for many years, Miss Sieber-Schumord, has been appointed director of the Institute of Experimental Medicine at St. Petersburg, in his place.

## THE ROENTGEN RAYS

IN DIFFERENTIATING BETWEEN OSTEOMYELITIS, OSSEOUS CYST, OSTEOSARCOMA AND OTHER OSSEOUS LESIONS, WITH SKIAGRAPHIC DEMONSTRATIONS.

CARL BECK, M.D.

NEW YORK CITY.

In periostitis, as well as in osteomyelitis, the skiagraphic signs are well marked. Abscesses can not only be localized, but their extent is so well outlined that the technical steps of the operation can be definitely traced in advance. The feeling of security the surgeon has while proceeding under the mentorship of the skiagraph gives a satisfaction unknown in former years, when often the whole femur had to be exposed simply in order to ascertain whether all foci were detected. If the Roentgen

Fig. 1.—Osteomyelitic focus in the middle of the humerus.

rays show but one focus, no other regions of the bone need be attacked.

In such cases a preceding trauma often opens the avenue of infection. The pain, the edema, the fever, and general debility may be sometimes so little marked that differentiation becomes difficult. The skiagraph not only clears this difficulty of diagnosing this disease, the true etiology of which is still so obscure, but it also furnishes a trustworthy guide for the operative technic at the same time.

Osteomyelitis is of a decidedly infectious character, generally due to the invasion of the staphylococcus aureus, which fortunately has a tendency of forming circumscribed foci in the vascular tissues of the bone, viz., the medulla, and sometimes the periosteum. The predilection of osteomyelitis is for the long bones of young

individuals. It is self-evident, therefore, that the early recognition of osteomyelitic foci renders the prognosis of their evacuation extremely favorable.

In the case of a lady of 20 years, the slow onset of the symptoms did not seem to indicate an acute inflammatory process. Pain at the thickened area of the middle of the humerus, being present only temporarily, the fear of a malignant growth was apparently not unjustifiable. The skiagraph at once did away with all anxiety, since it revealed the presence of periostitic proliferations and a circumscribed osteomyelitic focus (Fig. 1). The focus was easily exposed by the chisel, under the mentorship of the skiagraph. That the skiagraph has also spoken the truth by demonstrating the integrity of the remaining portions of the humerus, was shown by the speedy recovery of the patient.

The focus was distinguished by its light shade in the midst of the dark shadow of the cortex. The regularity of the cortical line and the external proliferation distinguished it from osteosarcoma, and the absence of distension from osseous cyst.

Necrosis and other later stages of inflammatory processes can be represented still more distinctly. The size and shape of sequestra can easily be made out. It can,

introduction of a probe did not reveal the presence of rough bone, and we were inclined to suppress our suspicion of the presence of a sequestrum. Our surprise was great when the Roentgen rays revealed the presence of a large splinter exfoliated from the inner portion of the radius, the surface of which was covered by osteophytes (Fig. 2). The direction of the skin incision, a slight oblique, was dictated by the position of the sequestrum as shown by the skiagraph. When the sequestrum was reached it was found to be covered by thick fibrous tissue at the upper surface, while the inner and lower surfaces were exposed. This explains why the introduction of the probe gave no positive information, since it had touched only the fibrous cover and did not come in contact with the rough lateral or posterior surface. Recovery was perfect eleven days after the operation.

Fig. 2.—Sequestrum, exfoliating from radius.

furthermore, be ascertained how they are located in their bony coffin and whether they still adhere or are exfoliated. Under the guidance of the Roentgen rays extraction is very easy.

In the case of a man of 23 years, who had crushed his left little finger, amputation was deferred until septic tenonitis and tenosynovitis had developed. The extensive tissue necrosis in the muscular interstices of the forearm necessitated free and deep incisions, which showed the radius, as well as the ulna, denuded of its periosteum. Amputation was therefore authoritatively advised, but nevertheless the chances for further conservative treatment were taken. Fortunately, the process became confined to the forearm and recovery seemed to make rapid progress. Only a small fistula at the dorsum of the forearm did not close. The repeated

Fig. 3.—Arthritic changes in the enlarged external condyle.

The regeneration of osseous tissue can also be well studied in such cases by the skiagraph. Foci of the same character are sometimes formed in typhoid fever. They must be treated after the same principles.

In diagnosing inflammatory processes in the joints, great difficulties are sometimes offered. As stated before, in the case of acute rheumatism, the integrity of the articular outlines are well marked. The same applies to acute inflammatory processes due to infection. In the latter event the distension of the joint by the serous or purulent effusion may be represented by the skiagraph. In chronic rheumatic processes the articular bone line appears somewhat irregular. In arthritis the contours of the bone epiphyses appear irregular, like indentations on some portions, while others are veiled. The arthritic deposits are recognizable as light shadows

of the deformed epiphyses, as they consist of translucent uric acid salts, while their periphery is distinguished by a dark sphere. In arthritis deformans the ositic proliferations are especially abundant and are well represented by the rays.

Figure 3 illustrates the case of a laborer of 50 years, who sustained an injury of his elbow eleven years ago. He reported that recovery took place after several months and that the elbow had remained stiff ever since. During the last few years inflammatory signs had manifested themselves, which were regarded as rheumatic. No other joints were involved. Since then he also had repeated attacks of pain in the elbow joint. When I examined the patient for the first time I found the elbow very much thickened and fixed at a sharp angle. Pressure below the external condyle caused intense pain. Crepitus, so often found in old arthritic processes, could

mean sometimes of differentiation from other affections, the clinical signs of which resemble it. The walls of an intra-osseous focus appear thickened. Some portions are translucent and their contours irregular. The articular outlines of a tubercular joint have lost their regularity and appear diffuse, cloudy and sometimes shaggy. In later stages, when cheesy foci have formed, for instance, their areas appear translucent. The cortex is sometimes entirely destroyed and leaves the impression of having been scooped out with a gouge. In most cases, especially when the soft tissues are also affected, atrophy is marked. Figure 4 represents the feet of a man of 58 years, who suffered from tuberculosis of the ankle joint for two years. He was treated by the injection of iodoform-glycerin and the administration of guaiacol carbonate. The left leg recovered entirely, leaving considerable deformity and

Fig. 4.—Tuberculosis of both ankle-joints.

not be produced in this instance, as the joint permitted no motion. There were no indications of tuberculosis, syphilis or gonorrhea. The skiagraph revealed the presence of mal-union (sideward displacement) of the coronoid process of the ulna, which probably had given the first impetus for the development of the arthritis deformans, the light shaded changes of which are especially well marked in the external condyle of the humerus. The left condyle shows synostosis with the olecranon. Removal of the projecting fragment by the chisel, separation of the adhesions, and the partial resection of the external condyle, the seat of predilection for the acute attacks, was advised as a therapeutic means.

In tuberculosis of the bones and the joints the Roentgen rays not only give information as to the seat and extent of the tubercular areas, but also offer the only

ankylosis only. The astragalus shows deformity and extensive destruction. The right leg is in an acute inflammatory stage, cheesy pus being present in the ankle joint. When there is calcareous degeneration the foci appear dark-shaded.

In the case of extensive tubercular destruction the eroded and displaced cartilages can be studied. In tubercular coxitis, the spontaneous upward dislocation of the femur and the separation of its head in the acetabulum can also be easily recognized.

The only marked signs of tubercular spondylitis consist sometimes in the presence of an abscess below Poupert's ligament, the nature of which would not be properly interpreted, if the plate did not prove the existence of vertebral changes.

It need not be said that the early detection of a tuber-

cular focus enables the surgeon to do a conservative operation, while at the late stage of extensive destruction such efforts are futile, as it is sadly illustrated by skiagraphic examination.

By realizing that so-called osteosarcoma is the most frequent of morbid growths and that of all tumors sarcoma offers the gravest prognosis, the importance of a thorough diagnosis need not be emphasized. The matrix of osteosarcoma, like that of all osseous growths, is either the periosteum or the medulla, in combination with the tissue originating from their proliferation.

Periosteal sarcoma is of a moderate hardness and contains either round, spindle or polymorphous cells. It attaches itself to the bone laterally, but may, in its further development, encircle it entirely. Periosteal sarcoma may become a real osteosarcoma at a later stage, when osseous trabeculae are formed. The skiagraph of periosteal sarcoma is characteristic, since it shows fine spiculated trabeculae that radiate from the surface. Periosteal sarcoma spreads rapidly and is highly malignant. Whenever the diagnosis of periosteal sarcoma is made, amputation should be insisted upon.

Sarcoma originating from the medulla is called myelogenous and is of a less malignant character. It may

fracture of the carpal end of the radius. But the consistency of the epiphyseal end was soft. The skiagraph failed to show the evidence of bone tissue, only one small remnant being left at the outer aspect of the radius. Resection was advised, but before the patient submitted to it another month had elapsed, during which time the neoplasm had grown to a great extent. The result was reported as being fair, eight months after the operation.

The hard myelogenous variety generally called endosteal or central sarcoma, also shows the ordinary sarcomatous structure. Its distinguishing feature is its fibrous texture and the presence of spindle cells. Some portions contain various tissues: the spindle-cell tissues often contain giant cells. If smaller or larger bone trabeculae are produced, it is called osteosarcoma proper:

Fig. 5.—Osteosarcoma of upper third of humerus.

be classified as soft, hard, alveolar and multiple. The soft myelogenous variety shows the ordinary sarcomatous texture. Its predominating feature is the presence of round cells. It has a decidedly more benign character than the periosteal type. Therefore it justifies a conservative attempt, that is, extensive extirpation. It produces carious destruction of the spongy portion which may cause spontaneous fracture. At a later stage the osseous shell will yield to the spreading sarcomatous tissue. This variety has a predilection for the long bones, especially their ends, and predominates at the lower epiphyses of the femur, tibia, humerus and radius. Skiagraphs of the soft myelogenous variety show the absence of osseous tissue, small fragments of it being sometimes left here and there.

In the case of a woman, age 28 years, who had fallen on her hand when it was in dorsal flexion, the faint outlines of boneshell in a soft myelosarcoma were shown. The swelling resulting from the injury produced the impression that a fracture of the carpal end of the radius was sustained.

Three months after the injury, when the patient came under my observation for the first time, a small deformity was noticed just as it is observed in a badly united

Fig. 6.—Osteosarcoma of lower end of radius.

if there are calcareous deposits, petrifying sarcoma; and if the tissues become vascular, a telangiectatic sarcoma will be formed, so that it may be mistaken for an aneurysm.

In later stages, when there is a regressive metamorphosis, fatty or cystic degeneration may take place. In this case, neoplasms that occur especially in the femur, tibia and inferior maxilla, may attain an enormous size.

The skiagraph of osteosarcoma proper (Fig. 5) shows more osseous tissue than the former variety, but its outlines are very irregular. Osteosarcoma proper usually commences near the epiphysis of a long bone. Skiagraph No. 6 shows the irregular sarcomatous proliferation of the lower one-third of the radius in a woman of 40 years. Treatment was not resorted to until two months afterward, when the skiagraph (Fig. 7) re-

vealed the destruction of the lower third of the radius and of a large portion of the carpus. Resection was performed; the result was perfect, as was illustrated by another skiagraph taken more than four years after the operation, which showed the regeneration of the osseous tissue.

The alveolar variety is characterized by its alveolar stroma, which contains nests of large cells. They have a predilection for the bones of the skull and the trunk. The multiple variety (also called myeloma) is characterized by the presence of numerous whitish foci, which consist of small round cells. It has the same structure as the lymphoid sarcoma and is nearly exclusively found in very old individuals, for whose skull and trunk they show the same predilection as the former variety.

The skiagraph of the alveolar, as well as the multiple type, shows the foci as light irregular shades. The structure of their type, especially their manner of destroying the pre-existing bone tissues, the thin osseous walls and the trabecular formation, is the standpoint for their skiagraphic study. The intra-osseous tension is responsible for the expansion of the compact osseous layer, which is thus made gradually weaker and at last almost

Fig. 7.—Destruction of lower third of radius and portion of carpus by osteosarcoma.

entirely disappears. Thus we see that it is the abnormal and indefinite outline, or even the entire absence of the osseous cells, the cortex especially disappearing, which is more or less characteristic for the various types of osseous sarcoma in contradistinction to other bone diseases.

As to differentiation, it may be said that in aneurysm the bone would show intact. Attention was called by me to the usefulness of the Roentgen rays in a case of femoral aneurysm, which, on account of extremely thick walls, showed no pulsation, so that originally it had been taken for osteosarcoma, an amputation then having been considered. The femur appearing intact, it was evident that there was a disease of the soft tissues.

In chronic osteoperiostitis the walls appear irregular, but the irregularity is one-sided and—exteriorly—there is a globular or spindle-like shape (see Fig. 1). In tuberculosis the shade will be cloudy or shaggy. In

osteomyelitis, the cortex shows nearly normal outlines (Fig 1).

The skiagraphic expression of syphilis is also characteristic. In the congenital form, large ossified areas are recognized in the epiphyses that would appear translucent in their normal cartilaginous condition. On the other hand, light areas are noted in the diaphyses as an expression of insufficient calcareous deposition. The synostosis between the cartilaginous epiphyses and the diaphyseal end appears as a very marked line, indicating the abundance of calcareous salts deposited there. Gumata show regular light-shaded foci. Their disappearance after the administration of iodid of potassium confirms the diagnosis.

Figure 8 shows the evidence of hyperostosis of the clavicle, scapula, ribs and the upper third of the humerus in a boy of 5 years. The pelvis, femur, tibia

Figure 8.

and fibula were similarly affected. The suspicion raised by the skiagraph was verified by the success of the specific therapy.

Osseous cyst showing the same clinical signs as osteosarcoma may easily be confounded with it. But in osseous cyst, while there is the same bulging as in osteosarcoma, the line of the cortex, on account of its thinness, appears narrow, but well marked and regular. The fluid center of osseous cyst renders the skiagraph translucent, the light shade showing the same regularity. The adjacent epiphyses are also normal in osseous cyst. The treatment of their various affections being difficult, the importance of a correct diagnosis is evident.<sup>1</sup>

Osteomyelitis, necrosis, tuberculosis, syphilis and osseous cyst demand conservative measures, while sarcoma calls for the most radical treatment. On the other hand, how painful must it be for a surgeon to find that because

1. "Osseous Cyst," Amer. Jour. Med. Sciences, June, 1901.

of his error of diagnosis such radical steps have been taken unnecessarily that, in other words, an extremity may have been amputated where only an osseous cyst existed, which could have been cured by simple incision.

It is, indeed, not very difficult to confound the two diseases, osseous cysts resembling osteosarcoma in its slow painless onset often preceded by an injury; in the gradual bulging of the area involved; and in their preference for youthful age and the long bones. These being characteristic features of osteosarcoma as well as of osseous cyst, it is evident that the differential diagnosis can not be made by considering the history, nor by inspection, nor by palpation.

The fact that the interior of the osseous cyst is filled with opaque bloody serum, and its walls are lined with a smooth coat, while in osteosarcoma solid masses are formed would indicate that an exploratory incision combined with microscopic examination would clear the question of diagnosis.

But the Roentgen rays give us more valuable information than the exploratory incision itself, and for the patient a Roentgen ray exposure is certainly more agreeable than an exploratory operation. Should an operation be decided upon, the microscopic examination can as well be made then.

At the early stage, osseous cysts, be they at the tibia or at the femur, are easily overlooked, the symptoms being insignificant. Sometimes there is a very slight pain that comes and goes. The joints are freely movable; and neither inspection nor palpation reveals any abnormality. After several months have elapsed the circumference of the extremity may appear very slightly enlarged, but it may not be before a fall on the thin shells of the cortex has produced a fracture that the symptoms are fully appreciated.

Other osseous diseases like osteoma, osteomalacia, rachitis and chondroma also offer some skiagraphic peculiarities in proportion to their various textures. Osteoma, of course, shows the shape of the osseous deformity, but there is a normal architectonic structure.

On account of the dissolution of the calcareous salts, osteomalacia is, similar to rachitis, distinguished by the absence of an osseous shade. In contradistinction to osteosarcoma, the whole bone appears translucent. In chondroma there is a regular light-shaded area of lobular shape according to its cartilaginous character.

Metastatic carcinoma in bones can also be represented.

## A CASE OF RELAXATION OF THE PUBIC JOINTS DURING PREGNANCY.

JOSEPH B. DE LEE, M.D.  
CHICAGO.

Mrs. B., age 39, XI para, four abortions, all deliveries normal. This pregnancy has advanced to the ninth month. Beginning at the sixth month, patient has had difficulty with the limbs and pain about the pelvis. The pains began on the right side over the sacro-iliac joint and have been getting worse there, also extending to the other sacro-iliac joint and to the pubis. Now the pain extends down the right leg, and all motions of the lower trunk and extremities are painful, being referred especially to the pelvic girdle, the pubis and the right side. Difficulty in walking has increased up to the present, locomotion at the present time being laborious and distressing. She can not cross the legs and all movements of the trunk and lower extremities are carried out with difficulty and pain. In sitting, down or getting up, she has to use the hands and arms, fixing the shoulder girdle and thus suspending the trunk. She can lie only on the side, and can not turn nor assume the erect posture without assistance. The pains and disability are worse

at night, worse upon beginning to move around, then better after being up a while, but get more unendurable as she becomes tired with exertion. There is no trouble with the bladder or the bowels, and no paresthesia.

Examination: General health fair; abdomen much distended, somewhat pendulous; uterus large; varicose veins in the legs and vulva, which patient says are quite painful. Patient sits on the edge of a chair with legs extended, slightly everted and abducted. There is an apparent paraplegia, but the patient can use all individual muscles; no sensory disturbances; knee jerks slightly exaggerated—as is usual in pregnancy. Abducting the thigh produces great pain at the pubis and at sides of the pelvis, as do nearly all passive movements of the legs. The patient herself says that all the trouble is "found around the pelvis." Pressure over the pubis creates outcry of pain, much less so when the rami are touched. Pressure over the center of the sacrum is not painful, but over the sacro-iliac joints is distinctly so, the demarcation being striking. Squeezing of the pelvis together from the sides is acutely painful, in fact, one thinks of an inflammatory affection of the joints.

Over the pubes a distinct separation of the ends for three-eighths of an inch can be felt, and, when the thigh is manipulated, the ends can be felt to ride on each other.

Vaginally the posterior surface of the pubis is very tender. The interval between the ends of the pubic bones is spanned by a tense elastic membrane, which can be pressed into the joint one-eighth of an inch. There appears to be no fluid in the joint, but this was hard to determine. Moderately extended movement of the thigh showed an up and down riding of the pubic ends of one-fourth of an inch. The tenderness extended down the rami pubis about two inches. There was no tumefaction of the ends of the bones. The sacro-iliac joints can not be palpated owing to the unruliness of the woman.

The history that this woman gives is interesting, but does not throw much light on the causation of the affection. Her mother died of tuberculosis; the father is living. She has had neither rheumatism nor any particular sickness. She menstruated early and regularly. She was married at 18, had a daughter within a year, another child within two years, and was six months pregnant with a third—now a boy of 17—when she "caught cold" and "had inflammation of the womb," being in bed for two weeks. Since that time she has had a persistent pain in the sacrum and the right side, which was especially marked during the numerous pregnancies that have intervened till now. Two or three weeks after delivery the patient has always regained her previous condition. At each succeeding pregnancy the pains and disability have gotten worse. They also begin earlier and the degree has been more marked until the present, when the patient is all but bedridden. She says, however, that in the last week or so there is a slight amelioration in the symptoms. A tight pelvic girdle had been used for a while without the slightest benefit. Counter-irritants and rest have helped, but at times the patient has needed narcotics.

The ancients taught that the pelvic joints always softened during pregnancy and opened during labor, so that the fetus could readily pass through. They ascribed difficult labor sometimes to the too great rigidity of the joints. Later the opposite was believed to be the normal, and those cases where there was relaxation of the joints were called morbid. Recent experiments, undertaken in behalf of the operation of symphysiotomy, show that there is some softening of the joints during pregnancy, and clinical experience confirms this.

The ancients must have reasoned from analogy, having observed the softening of the joints in cows and other animals. The "sinking of the rump" and the difficulty of locomotion of the cow show the veterinarian that the

animal is near term. In guinea-pigs the pubic ligaments soften and allow a separation of the bones sometimes to the extent of an inch. The legs may even be laid flat alongside the animal. After labor the joint again becomes firm.

In women, and, to a less extent, in men, there is some movement of the pelvic bones on each other during walking, and during pregnancy there is appreciable softening of the joints. While in these cases there may be no actual enlargement of the pelvis, such dilatation is possible, and, further, this softening of the joints permits movement of the bones on each other, which must be of service in the mechanism of labor.

Matthews Duncan is of this opinion. The writer would refer the readers to this monograph<sup>1</sup> for a further very interesting consideration of this matter, and will allude only briefly in this article to his own researches on this subject.

In the routine examination of pregnant women in the last months of gestation, I have almost always found some tenderness directly over the pubis. Careful palpation showed a long groove between the ends of the bones, and if, while the finger is pressed into the groove, the thigh be abducted and adducted, distinct motion of the bones at the joint will be appreciated. During labor this phenomenon is marked, and even late in the puerperium.

The same findings will be noted on the internal examination. The posterior pubic ligament will have to be pressed between the bones to elicit the groove, and this is somewhat painful. The riding of one end of the pubis on the other is easily felt. These findings are developed to a variable extent, and are, perhaps, a little more marked in multipara.

It is this softening of the joints which renders the Walcher position of value in the conduct of difficult labors, and the sacro-iliac joints in symphysiotomy are thus enabled to open partly. R. Braun von Fernwald, in 1895, demonstrated the mobility of the pubis in his studies of the after-effects of symphysiotomy. During labor one can, by putting the patient in extreme Walcher position, show a narrowing of the outlet, the tuberosities of the ischii approaching each other; then by changing to the extreme lithotomy the distance between the two tuberosities increases. When the head is passing the outlet it can be held back, and sometimes even be visibly pushed back, by dropping the legs as far as possible towards the floor.

The histologic changes in the joint have been studied on animals more than on the human. The joints partake of the general imbibition of the pelvis tissues, the cartilage is swollen, and there is not seldom a collection of synovial fluid in the sac. The separation of the joints may be actual or latent, developed only during labor.

Ordinarily the patient does not complain, but sometimes this condition is the cause of more or less distress during the pregnancy. These conditions are in line with those which were described in the case of Mrs. B., and the distinction between the normal and the pathologic is not easy to draw. The main symptoms are as follows: Pain in and about the pelvis, referred to the site of the joints, and especially to the particular one involved; difficulty in locomotion; easy tiring, with a general sense of weakness; inability to arise from a sitting posture; relief by walking, followed by pain in the pelvis, necessitating rest; the condition is worse in the morning, better in the day, and worse again in the evening; pain reflected up and down the nerve trunks of the pelvis, simulating

neuralgia, or even pains in the hypogastrium simulating abdominal disorders. When the patient is bedridden the case is decidedly pathologic. On examination no cause for the symptoms can be found till the condition of the pelvic joints is discovered. The tenderness of the pubic cartilage is the most prominent finding. The sides of the joint are painless, but pressure directly over the middle evokes lively expressions of suffering. Then the groove may be found. Deep pressure over the sacro-iliac joints elicits pain, but not over the coccyx. The gait is peculiar, wabbling, "like a duck" as one woman expressed it. A distinct rising and falling of the crests of the ilia can be seen which is not all due to the tilting of the pelvis. The distress in walking may sometimes be a real pain referred to the affected joint or joints.

The diagnosis is easy if the possibility of the condition be kept in mind.

So far as treatment is concerned, I have found nothing of permanent or constant benefit. The bowels should first be gotten into prime condition. The diet should exclude meat as far as possible, and diuresis should be encouraged with milk, buttermilk, water, etc. The patient must refrain from long walks and keep off her feet as much as possible, with a needed amount of exercise. The pelvic girdle has been recommended, but I have found very little, if any, benefit derived from it. Topical applications of stimulating liniments [Lin. chloroformi and ammoniæ, āā] have given temporary partial relief. The condition disappears rapidly after parturition. The patient should be encouraged by the information that the condition, though painful, will render labor easier and will disappear after it.

## Clinical Report.

### A CASE OF FATAL VACCINATION INFECTION WHICH RESEMBLED APPENDICITIS.

PERITONITIS FOLLOWING INGUINAL ADENITIS AND RETRO-CECAL PURULENT INFILTRATION.

F. H. RUSSELL, A.M., M.D.

Interne at Presbyterian Hospital. (From Prof. Fenger's Clinic.)  
CHICAGO.

On March 12 the patient, a female, age 15 years, was brought into the Presbyterian Hospital, presenting symptoms of acute appendicitis. She was in a state of semi-stupor. Her temperature was 102, and her pulse 120. The abdomen was quite tympanitic and very tender to the touch. There was marked muscular rigidity over the right side. She held her right leg in flexion and any movement of the limb caused intense pain.

Professor Fenger saw the patient in consultation soon after her entrance and decided to operate immediately.

Her stomach was washed out and she was taken to the operating room. After the patient was anesthetized a vaginal examination was made. This proved to be negative. The McBurney incision was made. As soon as the abdominal cavity was opened, some clear serous fluid was found. Cultures were made from this but unfortunately they were subsequently spoiled. The appendix was found free and uninvolved. The walls of the cecum showed quite marked infiltration. Nothing was found to account for the trouble. Farther exploration of the abdomen was not warranted on account of the poor condition of the patient, so the abdomen was closed and the patient put back to bed.

Her condition gradually grew worse. The pulse became more rapid and thready. Early the next morning it was 160 and two hours later it could not be counted. The temperature that night was 102, the next morning it was subnormal. She

1. Researches in Obstetrics, 1868, p. 146.

was restless and delirious after the operation; later she passed into coma and vomited several times. Death took place the next day about noon, twenty hours after the operation.

A complete autopsy was made by Professor Hektoen a few hours after death. The anatomical diagnosis was as follows:

Vaccination wound of the right leg; suppurative adenitis of the right inguinal and iliac glands; purulent intaration of the retro-cecal tissues; diffuse purulo-fibrinous peritonitis; recent laparotomy; acute splenic swelling and general parenchymatous degeneration; ecchymoses in lungs; hemorrhagic erosions of stomach and right adherent pleuritis.

The vaccination wound, measuring two centimeters in diameter, was located on the outer surface of the right leg below the knee. It was covered by a crust and healing by granulations.

The appendix was lightly imbedded in a fibrinous exudate. Its lumen was patent and its mucous membrane smooth. About it the intestinal coils were bound by slight adhesions and those in the pelvis were deeply congested.

The chief interest in the postmortem centered in the condition found in the right retro-peritoneal region. In the cellular tissue behind the cecum and in front of the muscle was considerable infiltrations of pus extending down toward the inguinal region. The deep inguinal and iliac glands were enlarged and soft; some of them contained small abscesses.

The examination of the generative organs, intestines, and bones of the pelvis and spine was negative.

Cultures from the purulent fluid in the abdominal cavity, from the heart's blood and from the inguinal glands showed a pure culture of the staphylococcus pyogenes albus.

In the histological examination, made by Mr. Johnson, all the internal organs were found intensely congested. In the liver were many areas of focal necrosis. The inguinal lymph glands, stained by Gram's method, showed a few groups of cocci among the closely crowded lymphoid cells. No cocci were found in the tissues surrounding the vaccination wound.

After the postmortem was made, the interest in the case led to further inquiry into the history of her sickness previous to coming to the hospital. This was kindly furnished by Dr. Kearsley, the family physician.

The patient had not menstruated. For some time she had frequently complained of sharp pain in the stomach immediately after eating. This was so severe at times that she would leave the table before finishing her meal. Six weeks before coming to the hospital she was vaccinated at school by the Health Department physician. A large number were vaccinated at the same time. Her previous vaccinations were unsuccessful. This time she became quite sick. Her mother says a large "lump swelled up" in her right groin. For several days previous to her illness she limped, leaning forward and to the right in order to save her right side.

Her sickness began five days before she was brought to the hospital. She was suddenly seized by a very severe chill in the school room. The teacher was alarmed, a carriage was procured, and the principal carried the patient from the room to the carriage. When she reached home her condition was as follows: temperature 104, pulse 130. She had vomited once. She complained of pain in her back, hips and lower part of the abdomen. During the next twenty-four hours she took small doses of calomel, vomited many times and had free evacuations from the bowels.

The second day her condition was much the same as the first, except that her temperature was reduced by antipyretics.

On the third day she complained bitterly of the pain in her right hip. She said the pain radiated from the hip across the lower abdomen. She lay with the right lower extremity fixed in extension. Flexion of the right thigh or any motion in it caused excruciating pain. There was tenderness on pressure over the posterior surface of the right hip. The abdomen was moderately distended and over the lower part there was a board-like rigidity. There was acute tenderness over the lower one-half, most marked on the right side.

Drowsiness amounting at times almost to a stupor was a marked symptom throughout the whole illness. The vomiting

ceased the third day. Her bowels moved each day by an enema and gas was passed. On the fifth day the enema was retained and it was necessary to pass a long rectal tube.

From the beginning of her illness the pain and tenderness gradually increased in the right lower quadrant of the abdomen and the tendency to stupor became more constant.

From a consideration of the facts stated it seems evident that this was a case of infection following vaccination. There was the local infection, and from the clinical history we are justified in assuming that this was followed shortly by an enlargement of the superficial inguinal glands; then proceeding along the anatomical course the infection traveled to the deep inguinal and iliac glands, later producing a purulent condition of the retro-cecal tissues. The close proximity of these tissues to the peritoneum rendered that cavity easy of access for the micro-organisms. A local peritonitis developed, which gradually became general.

Death following vaccination was of quite frequent occurrence for a number of decades following its introduction by Jenner. During the last decade, however, fatal cases have been very rare, owing to our modern antiseptic precautions and to a more careful preparation of our vaccination material.

This case, though, is of more than ordinary interest because it presents one more of the many conditions which must be taken into consideration in making a differential diagnosis of appendicitis. This emphasizes that the surgeon, in making a diagnosis, should have in his possession all the facts which go to make up a complete clinical history of his patient.

---

**Technique for Determining the Freezing-Point of Blood or Urine.**—Waldvogel describes his technique as follows in the *Archiv f. Exp. Path.*, xvi, 1 and 2: About 8 or 10 c.c. of the urine or blood to be examined are poured into a small test-tube with a rubber ring around the top. This tube fits into a larger one with a space of about 1 cm. between the bottoms of the tubes and of 2 or 3 mm. between the walls. Both are then placed together in the freezing ice and salt mixture. The temperature is determined by a small thermometer, graduated in fiftieths of a degree C., with a rubber ring around it also, to keep it from touching the walls or bottom of the tube when inserted in the urine or blood. When it registers  $-2^{\circ}\text{C}$ ., the fluid is stirred with the thermometer and it congeals almost instantaneously into a solid mass of ice. Diluting the fluid a little does not interfere with the determination of the freezing-point. Blood must be placed on ice for 48 hours before it is tested. The zero of the thermometer must correspond to the freezing-point of distilled water as verified from time to time.

**Post-Laparotomy Pneumonia.**—Henle stated at the recent German Congress of Surgery that pneumonia consecutive to abdominal operations is usually lobular, located in the lower lobe and more common on the right than on the left side. Most cases develop the second day. Their frequency increases with the age. Gastro-enterostomy, on account of carcinoma, is followed by pneumonia in 14 per cent. of the cases with a mortality of 9 per cent. The same intervention, done on account of a non-organic cause, is followed by pneumonia in 9 per cent. of the cases but no mortality. It is rarely observed after the radical treatment of hernia or "cold" appendicectomy, while it is comparatively frequent after celiotomy and incision of an abscess in the appendix region. The Schleich method of narcosis, according to the statistics, predisposes to this complication more than general narcosis. The most important factor is getting chilled, and since warm tables and tincture of soap instead of water have been used at Breslau, the number of cases of pneumonia has materially decreased. Kuemmel has observed 40 cases of pneumonia with 29 deaths in the course of 1070 laparotomies. The patients who succumbed were all cachectic, usually from malignant disease. Stolper proclaims that fatty embolism predisposes to pneumonia. This is liable to occur after any attrition of the adipose tissue, and attrition of this kind is frequent in laparotomies.

## THE STATE OF THE BLOOD ASSOCIATED WITH ADRENAL DISEASE.

From the first description by Addison of the symptomatology of adrenal disease, anemia has been considered one of the characteristic symptoms, but there have been wide differences of opinion as to the number of red and white blood corpuscles and the percentage of hemoglobin, both in animals from which the adrenal glands were removed and in human beings presenting evidences of adrenal disease. Addison himself reported a case in which the number of leucocytes was increased. Some observers believe that there is a reduction in the total amount of blood, and an alteration in its composition, rather than any numerical change in the formed elements. Others, however, have reported a marked diminution in the number of red blood corpuscles, as well as a marked deficiency in the amount of fibrin. By some, the blood conditions have been described as normal, while others have found an increase in the number of lymphocytes. The question is, therefore, one upon which further light is needed.

In two cases reported by Hamel<sup>1</sup> the condition of the blood was found practically normal, except for the presence of a relatively large number of lymphocytes. One of the cases terminated fatally, despite the employment, among other things, of adrenal extract; and postmortem examination disclosed caseous changes in both adrenal bodies, and also a calcareous bronchial gland with cheesy softening at the center. In the other case marked improvement took place, the treatment consisting essentially in the administration of easily digested food in generous amount, together with absolute rest in bed. Both cases presented an absence of hydrochloric acid from the gastric juice, and indicanuria was present in the first. There was evidence of old tuberculosis at the apex of one lung in the second case.

According to prevailing opinion, it is the function of the adrenal bodies to remove from the blood toxic products, and failure in the function of these glands will give rise to the symptoms of adrenal disease. These substances are evidently not true blood-poisons, as they do not give rise to the blood changes of anemia. The absence, in cases of tubercular disease of the adrenal bodies, of numerical changes in the cellular elements of the blood, notwithstanding the obvious anemia that is generally present, is attributable to a diminution in the

total amount of blood—a true oligemia—just as is so often the case in connection with pulmonary tuberculosis. This is supposed to be due to the destructive action of the toxins generated in the course of the tuberculous process. In cases, however, in which the adrenal glands are the seat of carcinoma, the blood changes of anemia develop, and this fact may be of diagnostic significance. Of course, the condition of the blood will be influenced by the presence of complications.

## EXPERIMENTAL DYSENTERY.

The interest in dysentery has received new impetus through the discovery by Thiga, of Japan, that one form of dysentery is caused by a bacillus of the colon-typhoid group. Investigators both in this country and elsewhere are now busy in studying the relations of this bacillus to the dysenteries observed from time to time in various places. The special form of dysentery known as amebic seems to be a distinct and definite disease. Its chronic course; the characteristic ulcers in the large intestine that result from a peculiar colliquative necrosis principally in the submucosa associated with the presence of a large number of amebæ in the tissues; the formation of peculiar secondary necroses with softening in the liver resulting in the so-called amebic abscess, are features that stamp the disease as *sui generis*. The failure to obtain the ameba in pure culture and to produce therewith experimental amebic dysentery in animals has prevented the definite establishment of the exact part played by the ameba coli in the causation of this interesting disease. At first it was thought that amebic dysentery occurred only in tropical and subtropical regions, but increased experience has proved that it may develop in permanent residents of temperate districts.

Recently Harris,<sup>1</sup> of Atlanta, Georgia, has reported the results of some interesting experiments upon young dogs. He did not succeed in producing any form of dysentery by the injection into the large intestine of great quantities of pure cultures of Shiga's bacillus. Similar experiments with cultures of the bacteria in the feces of patients with amebic dysentery also failed, while success was secured by injections of the feces containing the ameba. Hence he would draw the conclusion that the ameba is the sole causative agent of the dysentery in the young dogs experimented upon and which in every case proved fatal. The ameba was found in large numbers in and about the ulcers in the intestines of the dogs as well as in the diarrheal stools, which also contained masses of blood and mucus. In two dogs there developed also small abscesses of the liver. He adds a number of interesting histological details in regard to the ulcers and the abscesses of the liver. There seems to be no doubt, then, but that young dogs—older dogs are not susceptible—offer a favorable opportunity for the further study of the more exact genesis of the lesions associated with the amœba coli or dysenteriae.

1. Deutsches Archiv f. Klin. Med., 71 B., 2, 3 H., p. 240.

1. Virchow's Archiv, 1901, 166, 67-76.

It is therefore permissible to expect that further investigations will render more clear the method and manner in which are produced the peculiar and destructive lesions and the serious symptoms of amebic dysentery.

#### ORGANIZED MEDICAL DEFENSE.

The question has frequently been asked whether it would be feasible, practical and for the best interest of our profession for medical societies to take on themselves the defense of their members when sued for alleged malpractice, etc. On the ground that what affects the honor and standing of one member, affects the honor and standing of the entire profession, it would seem that the question should be answered in the affirmative. This view was taken by the New York County Medical Association at its meeting last month, when it adopted a plan for the defense of its members in such suits. There seems to be no good reason why the outcome of the plan<sup>1</sup> should not be as favorable as its projectors anticipate. There is certainly no question but that an organized effort on the part of the profession will have a tendency to deter blackmailers from bringing suits and will discourage pettifogging lawyers from working up such practice among the ignorant or dishonest classes. The public, too, will obtain a different impression as to the motives that usually instigate such suits.

While it is true that suits for malpractice are more commonly brought against surgeons, yet physicians are continually subject to these worse than annoyances. And, without doubt, this class of suits is becoming more frequent, for, unfortunately, those who have attempted this form of blackmail have found the general practitioner an easy prey. The physician attacked is too often ready to compromise regardless of the fact that he knows he has done only what is right. This compromise is made from the feeling that a legal defense would entail financial sacrifices, and the average physician in such a predicament would rather settle the case by the payment of a small sum or by giving up the collection of a just debt. By so doing he thinks that he would be avoiding an unprofitable and unpleasant notoriety at least.

If this compromising affected only the individual who compromised it would not be such a serious matter. But the fact is that every case so settled is an encouragement to the bringing of other similar suits and a breeder of other blackmailing schemes. It thus becomes a question of medical polity, something which concerns the profession as a whole. From this point of view—and it is the correct one—the physician or surgeon who compromises these claims is doing a positive injury to other members of the profession as well as to himself. If the result of these suits is something that affects the many, the many must step in and unitedly defend them. An organized defense is the only feasible way of meeting the rapidly growing number of blackmailing threat-

and alleged malpractice suits. This new departure in association helpfulness will therefore be watched with interest by other societies.

#### NEWER SIGNIFICANCE OF VENEREAL DISEASE.

All who are interested in the welfare of the race, as regards the confessedly growing danger from venereal diseases, are agreed that the most potent possible prophylactic factor under present circumstances is the spread of true ideas as to these diseases, their not uncommon significance for the deterioration of the general health, and their frequent obstinacy to effectual treatment. The necessity for the education of the public has been often pointed out. As a matter of fact, medical opinion in these matters has changed very much in the last twenty years, and at present there is no subject in medicine in which popular and scientific opinions are farther apart than as to the significance and curability of venereal disease. Of this change in medical opinion the general public is, unfortunately, unaware.

Since the discovery of gonococcus, medical knowledge has advanced so rapidly that even specialists have had to modify their views so frequently as to be almost discouraged at the prospect of ever reaching absolute truth. It is almost as needless to say as it is sad to confess that these advances in knowledge, far from making the absolute cure of the disease easier, have shown rather how obstinate to treatment the disease may prove. Long ago Ricard said jestingly: "We know when a gonorrhea begins, but the Lord only knows when it will end." Only in very recent years has the realization come as to how literally true the expression may be. Finger, the well-known Vienna specialist, says<sup>1</sup> that there are cases of gonorrhea which, after primary treatment, run an absolutely latent course as far as the patient is concerned, though they may be manifest to the physician and may demonstrate their presence by reinfection of the patient or by immediate infection of others. A-Jullien says: "An unobtrusive disease which hardly shows more than a trifling secretion, that causes no pain, does not affect the urine and does not stain the linen, is nevertheless susceptible of becoming virulently active, of taking on complications and of being transmitted." Continental authorities are not the only teachers of this frequent persistence of gonorrheal infections. Here in America, and in England, this fact is often insisted upon. Gaillard Thomas has said: "Specific vaginitis, transmitted by men who are utterly ignorant that the sins of their youth are at this late period bringing them to judgment, is one of the most frequent, most active and most direful causes of pelvic trouble in women."

It is this aspect of what has been called the milder form of venereal disease that the public ignores. A gonorrhea used to be compared to a cold in the head, and this mistaken notion, once a commonplace among medical men, still obtains outside the profession. The ne-

1. See page 43.

1. Last edition of his book, "Syphilis and the Venereal Diseases."

cessity for education in the matter is obvious. There is no doubt that the establishment of special lecture ships at the universities for the teaching of the true significance of venereal disease would be a source of good in this country like it has been in Germany. The temper of our people will not permit this eminently desirable addition to the general university curriculum, but it should be kept in mind as one of the advances in practical education that must come sooner or later. Meantime the family physician must pave the way for more public instruction by insistence on the change of opinion with regard to venereal diseases that has come to medical men during the present generation.

#### PRELIMINARY EXAMINATIONS FOR MEDICAL DEGREE.

Thus far there are three states in the Union that provide for preliminary examinations under state auspices of those entering upon their medical studies. These examinations are especially for those not possessing collegiate degrees or other satisfactory evidences of educational qualifications; in short, they are a state assurance of proper preliminary education. The need of this has been obvious in the past, and the legal requirement in these states is evidence of the opinion of the leaders in medical reform that it still exists. We are still cheapening our profession by admitting to it the unqualified and the competition of medical schools tends to render this evil a progressive one.

It is said that in Ohio since the enforcement of the preliminary education provisions of the medical practice act, and especially during the first year, there was a serious decline in the number of students in the medical colleges of the state, the colleges of adjoining states profiting in the same proportion. Nevertheless we find the medical journals of Ohio giving evidence of the satisfactory working of the law and congratulating the profession on the elevation of the standard that has been its result. Better equipped students are coming in from other states, recognizing the prestige that comes with higher requirements and even the beginning of the second year's trial of the law shows that the loss in numbers is likely to be but temporary. The requirements in Ohio and also in New York and Pennsylvania—a good high school education—are modest enough for admission to our higher class medical schools, but they are probably all that can well be exacted at the present time. There should be no relaxation in the demands, and the time will come—the sooner the better—when still higher exactions will be the rule. The misfortune is that state preliminary examinations, in default of other satisfactory evidence of the necessary preliminary educational requirements, are not universal, which results in a hardship to the schools in those states that have adopted this principle. It may be that any general movement to bring this about in the other states would arouse some opposition, open or otherwise, from a certain class of medical colleges; but if so, what harm? It

is well to know who are for progress and the best interests of the profession, and who are ready to sacrifice both for selfish personal and pecuniary considerations. Let those states that have good practice acts add this feature to them by additional legislation and let it be included when such laws are enacted in states that do not already possess them.

The public opinion that has chiefly to be educated in this matter is that of the profession itself. We have gone so long accepting a relatively inferior position—that is, relatively to what it should be—that we do not appreciate our disadvantages. Nevertheless we can not remain long in this blissful ignorance or permit any other kind of ignorance to be so much in evidence among us as it has unfortunately been in the past. The profitableness of the movement for better qualifications is already becoming evident to our Ohio brethren as it had already been to those in New York and Pennsylvania. The sooner the rest of the country realizes the fact and puts its knowledge into practice the better. There is no possible excuse nowadays for the admission to our medical colleges of those lacking in preliminary education. High schools, colleges and universities are within reach of the poorest.

#### THE COCAIN HABIT.

It appears that the cocaine addiction is, thus far, more a particular vice of the lower classes, but as such it seems to be spreading all over the world. According to Anglo-Indian papers it has become so prevalent among the street boys and school boys in Calcutta that the government has had to take the matter up with the idea of devising means for checking the evil. While as yet it is confined to the classes mentioned, it is feared that it will spread to others. In our own country it is particularly a vice of the Southern negro, and some states and municipalities have already legislation on the subject. The policy in India as regards opium has been thus far for revenue only, and it will be interesting to observe what will be done as regards cocaine.

#### STATE REGULATION OF MEDICAL COLLEGES AND MEDICAL EDUCATION.

One of the encouraging signs of the times is the evident interest in medical education taken by those outside of the profession. The latest is contained in the report of Prof. Delos Fall, State Superintendent of Public Instruction of Michigan. His recommendations are based on the results of a study of reports made to him by those appointed to inspect business and medical colleges. The following are his recommendations regarding medical colleges:

A standard of preliminary education should be required, and a board created to examine all students before entering upon the study of medicine. Some safe, uniform standard for graduation ought to be fixed and insisted upon as a condition precedent to a license to practice medicine. The financial solvency and stability of each institution should be more carefully guarded and insisted upon. Medical colleges should not be chartered in small towns where clinical and hospital facilities, so necessary to the proper education of a physician, are not

ordinarily found. A constant and thorough visitation and inspection of such institutions should be regularly made by a board of visitors competent to fairly judge of their merits. The capital of every medical college should be large enough to warrant the employment of men learned in their profession and the provision of equipment in all branches adequate to promise a proper medical course.

#### THE NATION SHOULD PAY THE LATE PRESIDENT'S PHYSICIANS.

It is reported that the executors of the estate of the late President McKinley have felt obliged in the course of their duties to ask for the bills of the physicians who attended him. These bills probably under the law constitute a legal claim which has to be met or waived by the creditors, hence the request. But it is not a matter for surprise that the surgeons are reluctant to send in their bills, which would naturally be large on account of the responsibility assumed and the other peculiar circumstances of the case. However, while the Ohio laws may require this action on the part of the executors, strict justice does not require that what the late President left should be depleted by the charges. He was stricken down at a public function while performing his official duties as President of the United States, not as a private individual, and the Nation is properly responsible for the expense which was incidental to his public position. There ought to be no question as to this point and no hesitation on the part of Congress to make an appropriation for the purpose. A corporation—as a railroad company—always considers it its duty to assume the expense of caring for its servants when injured in the performance of their duties. The Nation can certainly do no less in regard to its servants.

#### SUBSTITUTION EXTRAORDINARY.

Substitution as generally understood is one of the abominable evils against which physicians have to be on their guard. The only way to get rid of this evil is for a physician to insist on having his prescriptions filled by a reliable druggist, and then watch this druggist occasionally to see that he does not fall from grace. The reputation of the physician, the health, and sometimes life, of the patient depend on the correct filling of prescriptions. While we believe that very few druggists are guilty of substitution, some of them are. We refer now to the substitution of "something just as good" for a similar preparation and which the druggist may believe will answer the purpose, especially if it is cheaper. But the druggist who places his "belief" above the written instructions of the physician will be dishonest in other ways and should be treated accordingly. Our attention, however, has been called to another form of substitution that is more dangerous, more vicious, and more criminal than that referred to above, and one that is more difficult to guard against. We have received a circular letter from the Farbenfabriken of Elberfeld Company, in which they record their experience in ferreting out a despicable adulteration of their product. The facts in the case were brought out in a lawsuit and revealed that certain men were actively engaged in counterfeiting labels and boxes and filling them with all sorts of material utterly unlike the genuine and then selling them to druggists as the real article.

While we believe that this form of adulteration is unique to this particular instance, it is well that we recognize the possibility of such an occurrence in the future. It is further quite probable that this form of fraud would be worked only on unscrupulous druggists who desire to buy the cheapest without regard to quality.

#### HUMAN AND BOVINE TUBERCULOSIS.

The New York physician who recently inoculated a young woman with alleged bovine tuberculosis has thus far succeeded in obtaining notoriety, which was probably what he desired. But the notoriety he has received is not altogether a desirable one. His experiment was poorly conceived, lacked many of the essentials for a satisfactory scientific proof of what it was intended to show, and is at last discredited by the findings of the Brooklyn health authorities that his inoculated cow did not have tuberculosis. If the young woman has the disease, as he asserts, it must, therefore, have been from some other cause. As regards the ethics of the performance there can be but one opinion. Had he been confident that Koch's views were correct and that there was no danger in the inoculation, he would have a better case, but the reverse of this was the fact, and the general impression left by the performance as to his regard for human life is not pleasant. If the woman should die, whether from consumption or any other infection introduced by the inoculation, his position would not be an enviable one. It would have been more chivalrous as well as more generally creditable to him if he had tried his experiment on himself and had left somebody else to observe the effects. Perhaps the profession would have profited more had this been the course followed.

#### THE EFFECT OF ALCOHOL ON NATURAL IMMUNITY.

For years the venerable N. S. Davis has fought the use of alcohol as a therapeutic agent, maintaining in the face of a more or less general professional opinion to the contrary that alcohol even as a drug is dangerous and detrimental. This teaching in regard to alcohol seems to be gaining ground and is receiving notable reinforcement from recent experimental investigations in regard to the action of this substance in infections in animals. The work of Abbott and of Laitinen, already commented upon in these columns,<sup>1</sup> shows conclusively that alcohol increases the susceptibility of animals to infections. Most of the experimenters have employed rather large quantities of alcohol, quantities relatively so large as to be directly toxic. In order to avoid the criticism likely to be brought against the applicability to human medicine of the results of these experiments in which large doses were used, Goldberg<sup>2</sup> studied the influence of small doses upon natural immunity as illustrated in the case of the pigeon with respect to *B. anthracis*. The pigeon is relatively little susceptible to anthrax infection. Goldberg, using a brand of Russian spirituous fluid containing 40 per cent. alcohol and no fusel oil, found that 3 c.c. make a pigeon more or less intoxicated; further, that medium and large non-intoxicating doses of alcohol

1. THE JOURNAL A. M. A., 1900, Sept. 8.

2. Centralbl. f. Bakt., Abtheil. I, 1901, xxx, 696-700, and 731-741.

materially reduce the immunity of pigeons to anthrax. Chronic alcoholic intoxication of pigeons also has the same deleterious effect; and small doses of alcohol have no therapeutic effect upon experimental anthrax in pigeons infected repeatedly with fatal doses of anthrax bacilli. Here we have another set of experiments, the results of which are directly unfavorable to alcohol. Like the results of other researches in the same line they do not furnish the slightest support for the rational use of alcohol in human infections. While it may be urged that the results of animal experiments are not directly applicable to human pathology it should be remembered that microbic infections as a rule follow the same general laws in animals as in man. In both cases the mechanisms of reactions to infection have a general likeness. There seems to be no question but that alcoholics are less able to withstand various infections than the abstinent. The gravity of pneumonia in the alcoholic is well known. To this extent at least clinical experience tallies with animal experiment, and it certainly behooves the physician to assume a decidedly skeptical attitude with respect to the often very free use of alcohol in the treatment of infections.

#### THE ADMINISTRATION OF IMMUNIZING SERUM BY MOUTH.

A prominent serum expert of St. Louis, one of the members of the coroner's committee to investigate the recent cases of tetanus in that city, attributes in part to an immunizing effect of internal ingestion of antitoxin, the fact that a few took the disease who were exposed by inoculation with the infected serum. In at least fifteen cases, he says, the development of tetanus was prevented by the administration of the serum by the mouth. It is not exactly clear why this was done; but the expert in question says that it was in cases in which it was intended to immunize the members of the family surrounding the diphtheritic individual. It would seem from this statement that some of these must have contracted diphtheria and received injections of the contaminated serum, which did not cause tetanus in them because of its previous ingestion. This will be, to most of the profession, a new method of immunization, though there has been in the past occasional mention in the literature of such administration. That it should have been so extensively and so effectively practiced in St. Louis is certainly remarkable. In this connection a report that comes from Iowa may also be mentioned. The State Board of Health is there confronted with the problem, whether this method of producing immunity is reliable against another disease, smallpox. A homeopathic doctor, it appears, has been giving certificates of protection to school children to whom he had administered supposed vaccine in the form of pills. The question of their efficiency has been relegated to a committee of the Board and its decision is expected at the coming meeting. There are contingencies of this form of treatment that ought to seriously affect its popularity were their possibilities generally understood. If the mucous membrane can absorb the vaccine or other antitoxin, as it must for this method to be of any value, what insurance is there against unpleasant local gastric or intestinal complications and

what dosage is safe in this regard while otherwise effective? If the method is harmless because the absorbent power is slight or the gastric secretion destructive, the assurance of protection is lessened if not vitiated altogether; at least this would seem to be the case with diphtheria antitoxin. With vaccine, on the other hand, unless the secretions are protective any slight stomach or intestinal lesion of continuity, such as often exists without the knowledge of its owner, might produce very uncomfortable results. Either horn of the dilemma has its unpleasant aspects and one can only agree with the St. Louis expert when he says that this method of administration for immunizing purposes is not to be generally recommended. It is surely not supported by scientific investigation and evidence, and it certainly is not appetizing or otherwise esthetically attractive.

## Medical News.

### CALIFORNIA.

**Los Angeles Hospital** has been incorporated with a capital stock of \$25,000.

**Pasadena Hospital** received a Christmas gift of \$1000 from E. M. Fowler, Detroit, Mich., to be used in the purchase of surgical instruments and appliances for the operating room.

**Fight Against Medical Law Futile.**—In the case of the five Oakland individuals accused of practicing medicine without permits from the State Board of Medical Examiners, the court decided that the arguments urged against the constitutionality of the law creating the board were not such as should be sustained. He therefore overruled the demurrers and ordered the defendants to appear for trial.

**Consumptives Barred.**—Immigration Commissioner Hart H. North, San Francisco, has made a ruling which will prevent any alien consumptives from entering that port. The practice has been in the past to discriminate between consumptive steerage and saloon passengers. Mr. North has communicated with the authorities at Washington, and in accordance with several decisions already rendered he has decided that there is to be no class distinction and that all must be treated alike.

### DISTRICT OF COLUMBIA.

**Hospital for Foundlings.**—The Secretary of the Interior has recommended to Congress an appropriation of \$6000 for the maintenance of the Washington Hospital for Foundlings.

**Casualty Hospital.**—Dr. H. Wood Tobias has tendered his resignation as resident physician and has been appointed resident physician at the Columbian University Hospital. He is succeeded by Dr. Paul L. Freeman.

**To Aid the Blind.**—The Board of Charity has recommended to the District Commissioners that the Aid Association for the Blind be allowed compensation at the rate of \$10 per month for blind persons. The board recommends that the compensation be made from the appropriation for the relief for the poor.

**To Regulate Sale of Milk.**—Senator Gallinger has introduced a bill to regulate the sale of milk and cream in the District of Columbia. It provides that no person shall sell or produce for sale milk or cream without a permit from the Health Officer. The granting of the permit is to be conditional with the compliance with sanitary conditions prescribed by the health officer.

**School Inspection.**—The Legislative Committee of the Medical Society of the District of Columbia have endorsed the action of the commissioners in recommending the appropriation of \$5500 by Congress for the medical inspection of the local public schools. It is intended to appoint eleven medical inspectors at a salary of \$500 per annum. It is expected that the positions will be filled from among the competent physicians in the city.

**To Prevent the Sale of Unwholesome Food.**—The health officer has recommended the following regulation governing the sale of meats, and the same has been approved by the commissioners. No person shall sell or offer for sale in the District of Columbia any sheep or lamb slaughtered for food until the pelt, head and feet thereof shall have been removed. Any

person violating the provision of this section shall upon conviction thereof be punished by a fine of not less than \$5 nor more than \$25 for each and every offense.

**Surgeon-General Sternberg's Report.**—The Surgeon-General reports that under the contract made by him under the act of Congress for the care of indigent sick, the Providence Hospital has admitted during the past year 1576 patients with a monthly average of 142. He also reports for the Barnes Hospital at the U. S. Soldiers' Home that 838 sick soldiers were admitted during the year. He states that there has been a decided increase in the number treated during the past two years as a result of army casualties incident to the recent campaigns in the war.

**Water Supply of Washington.**—Washington City has in all probability the worst-appearing and the most unhealthy water for drinking purposes of any large city in the United States, and possibly of any city in the world. Recently the water has been of a dirty-brown color with large particles of solid matter floating throughout. The Marine-Hospital Service universally reports the presence of a large number of typhoid bacilli, and their report is corroborated by the chemists of the Health Department. The large number of cases of typhoid fever in the District has attracted special attention, and in consequence of the notoriously unhealthy character of the water, and the many appeals of the local government and the citizens, it was generally agreed in Congress that a suitable filtration plant should be provided as an adjunct to the local reservoir as a necessary prevention of typhoid and other diseases. This expectancy of the District, however, is greatly jeopardized by the action of the Secretary of the Treasury in refusing to approve the recommendations of the District Commissioners for the amount of the appropriations deemed necessary by them after the most careful consideration and exercise of the greatest economy. It is sincerely hoped that Congress in its wisdom, and in the full appreciation of the menace to the public health in consequence of the filthy water supplied to the citizens of the District, will agree on the estimates furnished by the Commissioners of the District and provide, among other things, the absolutely necessary filtration plant.

**Resolutions of the Medical Society in Lunacy Cases.**—Dr. D. S. Lamb, president of the District Medical Society, has forwarded to the Commissioners a copy of a resolution adopted by the Society relative to the disposal of lunacy cases. He asks the Commissioners to take such action as is best adapted to secure its enactment in the new District code. The resolution is as follows:

*Resolved*, That the Committee on Legislation be authorized and directed to take such action as is, in its judgment, best adapted to secure the enactment of the legislation as follows:

1. Legislation providing for the detention of alleged lunatics pending the formal adjudication of the question at issue, whenever, in the judgment of two physicians of not less than three years' experience and permanent residence in the District of Columbia, such alleged lunatics are, if unrestrained, dangerous to themselves or to others, or are so situated that their environments will if continued unchanged until after such formal adjudication seriously militate against their chances of improvement or recovery.

2. Legislation authorizing the appointment of trustees to take charge of the property of persons not insane, but rendered mentally incompetent by the habitual use of drugs of any sort, in the same manner as the proposed section 115 of the proposed code of laws for the District of Columbia, prepared by the Committee on Legislation of the Bar Association, seeks to authorize the appointment of trustees to control the property of persons addicted to the use of intoxicating liquors.

**Authority for the Army Medical Corps.**—Mr. Hay, of Virginia, has introduced a bill in Congress to define the duties of the Medical Department of the United States Army.

The object of the bill, "is to prevent epidemics of preventable diseases in the army by giving to the medical department the power to control the sanitary conditions of camps and posts, and to place responsibility somewhere as to the health of the army. As the law now is, there is no responsibility anywhere for conditions which have cost many thousands of valuable lives, and have caused the country to pay many millions of dollars, when both could have been saved by proper legislation. There is no intention to take from the line officer in command any necessary military power. This question has been like so many others brought home to us as a result of the Spanish war. The results of present laws and army regulations were shown up with startling distinctness during the war with Spain. It is not necessary to name any particular camp; it is well known that such preventable diseases as typhoid fever, dysentery, etc., were rife in almost all of them from May, 1898, to June, 1899, the total deaths in the army was 6,619; of these 3,116 resulted from typhoid fever, dysentery, and diarrhea, all preventable diseases. Two thousand seven hundred and seventy-four of these deaths were from typhoid fever."

Mr. Hay says there were many thousands who recovered, but many of them are drawing pensions, or have applied for them; 6000 pension claims have been allowed to Spanish-American war soldiers, some 45,000 claims are still to be adjusted. About 1 to 7 has been the average allowed. A careful exam-

ination of this list will show that the two-thirds of these claimants are men who were disabled by preventable diseases, or for the representatives of men who died from these diseases. The cost to the government of such conditions is beyond computation; pensions to the disabled, pensions to widows, and dependents, the cost of replacing the dead, all of these things pile up the expenses of maintaining the army and government.

## ILLINOIS.

**Dr. G. W. Miller**, Woodson, is seriously ill with cholelithiasis.

**St. Anthony's Hospital**, Rock Island, has been incorporated, the object of the corporation is to maintain a hospital and a home for the aged, and care for and educate orphans.

**Smallpox in an Asylum.**—The daily press of December 31 announces an outbreak of smallpox in the Home for Feeble-Minded Children at Lincoln. The institution contains over 1000 children and 183 officers and attendants. Over 100 cases are said to be in the Home.

**City Health Board Loses.**—Dr. Walter Ryan, Springfield, who was arrested at the instance of the city for failure to report a case of smallpox, as required by the city ordinance, was found not guilty. Dr. Ryan and the city physician differed as to the diagnosis, the city physician believing the case to be one of smallpox, while Dr. Ryan's diagnosis was chicken-pox.

**Smallpox.**—A few days ago 47 smallpox patients were hauled over 15 miles of rough country roads from East St. Louis to Belleville, because of a dispute of the local tradesmen with the authorities regarding payment for supplies furnished. —Palmer has a case of smallpox. —Posey now has 25 cases, an increase of 21 in a week. —Astoria reports one case. —Virden township has filed a bill against the county for \$1950 for expenses incurred in its epidemic of smallpox between October 14 and November 4.

**Reports of Births and Deaths.**—The State Board of Health has sent circulars to all physicians in the state calling their attention to the "Act requiring reports of births and deaths, and the recording of same; regulating the interment or other disposal of dead bodies, and prescribing a penalty for non-compliance with the provisions thereof," which became a law, January 1. The sections of this law relating to report of birth and disposal of the dead read as follows:

Section 1. It shall be the duty of every physician and midwife in the State of Illinois, who attends the birth of a child, to report said birth within thirty days after its occurrence to the county clerk of the county in which said birth takes place. Such reports shall be made on blank forms, to be prescribed and issued by the state board of health, and shall contain such information as may be directed by said board in resolutions, copies of which shall be printed on the reverse of the blank forms aforesaid. When no physician or midwife has been in attendance, then it shall be the duty of the parent, or in case of the disability of the parent, of the householder, to make said report within the time and in the manner aforesaid.

Section 2. Every physician, midwife, parent or householder, who shall comply with the foregoing provisions shall receive for each report of birth made in the manner directed by the state board of health, the sum of twenty-five cents. At the close of each quarter of the calendar year the county clerk shall certify to the county treasurer a list giving the number of births reported to him, and the names and addresses of the persons reporting the same, and payment therefor shall be made by the said county treasurer to the persons named in said list: Provided, That no duplicate report shall be paid for.

Section 3. No person shall inter, cremate, deposit in a vault or otherwise dispose of any human body, until he has received a permit so to do, as hereinafter provided, which permit shall bear date when issued, shall state the name of the deceased, the date and cause of death, the manner in which body will be disposed of and the place of such disposal, the name of the person to whom the permit is issued, and the name of the attending physician, midwife or coroner, and shall be signed by the official by whom it is issued.

Section 12. Any person or persons who shall violate any of the provisions of this act, shall be deemed guilty of a misdemeanor, and upon conviction thereof, shall be fined not less than ten nor more than one hundred dollars, or shall be imprisoned in the county jail not to exceed thirty days, or shall suffer both such fine and imprisonment in the discretion of the court.

The board expresses the hope that this law will meet with the approval of the profession and that in its enforcement the board will receive its hearty assistance and co-operation. A rigid enforcement of the law will not only furnish to the board statistics of incalculable value, but will place Illinois at the head of all states in the matter of vital statistics. While in many states there are efficient systems of registration of deaths, in but one or two are births completely registered at the present time.

## Chicago.

The Illinois Medical College held the opening exercises of its January term at its new college building, Washington Boulevard and Halsted Street, January 2. This building was

recently purchased by the college at a cost of \$50,000, and has been remodeled and newly furnished at a cost of \$15,000.

**Medical Staff Candidates Examined.**—The civil service commission held an examination under the direct charge of Drs. John R. Neely and Daniel R. Brower for internes at the County institutions. Of the 14 applicants 4 were women. Eleven of those who took the examination were placed on the eligible list.

**Consumptives Seek Shelter.**—The continuance of cold has driven consumptives in large numbers to the consumptive hospital at Dunning, materially interfering with the plans of the County Superintendent to utilize a portion of the hospital for the relief of the over-crowded condition in the hospital for the insane.

**Low Death-Rate.**—The statistics of the city health department show that the total mortality of 1901 will not exceed 24,300 and, figured on the minimum midyear population of the United States census office, 1,758,000, the annual rate per 1000 will be about 13.8—the lowest ever recorded for this or any other city of more than 1,000,000 population. The lowest previous rate—based on the United States census figures of population—was 14.36 per 1000 in 1897. For the previous ten years, 1890-1900, the average mortality rate was 17.67, or 21.8 per cent. higher than this probable rate for 1901.

**Cook County Hospital Needs.**—In his report to County Board of Commissioners, made December 23, Dr. Denslow Lewis, president of the attending staff of Cook County Hospital, made the following recommendations:

1. The construction of a separate building for skin and venereal cases. He suggests that a three-story building be erected, the first floor of which might be utilized by the County Agent for the storage and distribution of supplies.

2. Some provision should be made by the proper authorities for the care of inebriates. This includes the victims of epilepsy, apoplexy, mild insanity, heart or kidney disease, the sandbag or other form of assault or accident, who may be found unconscious on the public streets, and who are usually considered to be under the influence of alcohol. A separate building should be provided for the care of alcoholics, under the direction of the attending staff.

3. A children's pavilion apart from the hospital building is desirable. It is often advisable to permit the little patients to get out of doors, and for that reason their ward should be on the ground floor.

4. Provision for the x-ray work will have to be made. Probably \$1500 will be needed. The laboratory is now nearly completed, and the funds from the sale of clinic tickets, together with the amounts received from voluntary reduction of salary on the part of the president and certain commissioners, will probably be sufficient for its maintenance. A photographic outfit will be needed later in the year.

5. A card index system for the proper compilation and preservation of the history sheets and other records is a necessity if periodical bulletins are to be issued showing the scientific work done at the hospital. The appropriation of \$1,000 made for this purpose last year was not used because the laboratory was not completed, and it was impossible to furnish full reports of cases without instancing the pathologic findings.

## IOWA.

**Dubuque Detention Hospital,** which has just been finished, has been inspected by the Board of Supervisors and approved. Its equipment will be provided for at once.

**Iowa Methodist Hospital.**—The Hospital Association has provided for the \$30,000 indebtedness on the hospital at Des Moines and has decided to erect a new building, to cost \$50,000.

**Doctors Disagree.**—Dr. James P. Scroggs, Lenox, who sued Dr. A. W. Fees, of the same place, for \$5000 damages suffered by the plaintiff by reason of an article in a local paper reflecting on his professional reputation, has been awarded \$800 damages.

**Smallpox.**—On the Winnebago Reservation 39 deaths have occurred and 11 are now ill with the disease.—In Lincoln and Stanton townships, 15 cases were found.—Council Bluffs has had 29 cases this season.—In Pekay, north of Eddyville, there are 50 cases of the disease.—Dr. John T. Tweedy, Tabor, presented a bill for \$2025 for services to smallpox patients for 45 days; but the authorities allowed only \$786. He has now instituted suit against the supervisors of Fremont County for the full amount of his claim.

## MARYLAND.

### Baltimore.

**Dr. Francis Randolph Packard,** Philadelphia, lectured before the Book and Journal Club, December 21, on "The Resurrectionists of London and Edinburgh." The lecture was followed by a smoker.

**Dr. L. O. Howard,** chief of the Division of Entomology, Department of Agriculture, lectured December 16, before the

Biological Club at the Woman's College on "Mosquitoes and Their Relation to Disease."

**Mortality of Baltimore.**—For the week ended December 21 there were 175 deaths, an annual rate of 17.56 per 1000. Among the causes of death were pneumonia, 25; tuberculosis, 20; Bright's disease, 17; heart disease and cancer, each, 6; diphtheria and broncho-pneumonia each 4, and typhoid fever, 3.

**Northeastern Dispensary Opened.**—The new building of the Northeastern Dispensary was opened December 17. Dr. A. D. McConachie was elected one of the directors and dean of the staff, which includes Drs. G. C. E. Vogler, J. W. Williams, S. Rosenheim, C. N. Branin, J. C. Beck, P. E. Lilly, W. M. Pearce, D. L. Dunott, S. H. Likes, T. M. Guier, and G. E. Starr.

**Cancer and Smallpox.**—The Health Commissioner reports between 400 and 500 fatal cases of cancer in this city during 1901. The disease has increased out of proportion to the population and an investigation is to be made into the matter. Smallpox has occurred here for 50 years in decennial epidemics; so far the city has escaped this year, although this is the year in which it is due.

**Personal.**—Dr. A. D. McConachie, who has been connected with the Presbyterian Eye and Ear Hospital for ten years, has resigned.—Dr. B. Bernard Broune is suffering from an infected wound of the hand received in an operation.—Capt. Wm. F. Lippitt, Jr., late assistant surgeon, serving in the Philippines, and who was severely wounded in the defense of the consulate at Peking, has been ordered to duty at Fort McHenry, vice Dr. A. N. Stark, ordered to West Point.—Dr. Jesse C. Coggins, assistant physician at the Maryland Hospital for the Insane, Catonsville, sails for Europe today for the purpose of observing and studying the methods of caring for the insane in vogue there.

## MICHIGAN.

**Doctor Wins.**—A suit for malpractice with \$10,000 damages against a Middleville physician was decided by the jury, for the defendant, December 23.

**Ex-Convict an Illegal Practitioner.**—A colored man of Jackson, who was recently released after serving a term of five years in the state penitentiary for burglary, was recently fined \$90 with an alternative of 90 days' imprisonment, for the illegal practice of medicine.

**Smallpox.**—Dr. M. Clark Woodmansee, Hartings, is ill with smallpox.—The disease has broken out among the Indians at Lake Vieux Desert, and is also prevalent at Crooked Lake.—At Muskegon, 17 cases have been reported.—At Birch Run, the school and churches have been closed, and all public meetings prohibited.—Potters, Calumet County, is under strict quarantine on account of 12 cases of the disease.—Two new cases have appeared at Menominee.

## MINNESOTA.

**St. Luke's Hospital,** St. Paul, profited to the extent of nearly \$2000 by the charity ball recently held.

**Swedish Hospital, Minneapolis.**—The new building is so nearly completed that patients will be moved into it from the old building in a few days.

**New Hospital.**—The contract for the construction of the new hospital for Two Harbors, has been let and the work has already commenced. The building is to cost \$25,000.

**Dr. Appleby Wins.**—In the suit of Simon Aramowsky against Dr. T. E. W. Villiers Appleby, St. Paul, for \$3000 for alleged malicious prosecution arising from the care of a child of the plaintiff, who was treated by Dr. Appleby, the jury was instructed to find for the defendant.

**Increase in Smallpox.**—During the fortnight ended December 16, 530 new cases were reported in the state, an increase of more than 100 per cent., as compared with the preceding two weeks. An increase in the localities affected is also noticed from 72 to 119. The disease is thus far of a very mild type, and no deaths are reported. Red Lake Falls reports 39 cases, the largest from any one locality. The total number of cases in Red Lake County is 50. Clay County reports the largest number of cases of any county, 67; 18 of the cases are in Georgetown township, and Goose Prairie and Highland Grove townships each report 14 cases. Chaska reports 24 cases, and Carver County sends in a total of 56 cases. Perham township, Otter Tail County, reports 21 cases, and the county 56. Other counties reporting a considerable number of cases are: Norman County, 28; St. Louis County, 26; Pipestone County, 25; Marshall County, 25; Kittson County, 21; Polk County, 15; Hen-

nepin County, 13; Crow Wing, Jackson and Mille Lacs counties, 11 cases each.

#### NEW JERSEY.

**Camden Health Board.**—At the meeting of the Board, December 23, it was reported that during the month there had been 32 cases of smallpox. A corps of 24 physicians is to be appointed to make house-to-house vaccinations. They are to be paid a fee of 50 cents for each vaccination, and a like amount for each revaccination.

**Medical Library for Trenton.**—The Trenton Medical Library Association met, December 17, and gave power to its executive committee to accept the offer of the Public Library commission to set apart a room in the Free Public Library for medical books, papers, etc., and to buy one book for every one furnished by the association. It was decided to invite all physicians, surgeons, dentists and veterinarians to join the Association, to ask each member to give what he thought was right to the fund to purchase books, the amount to be considered initiation fee and first year's dues. After the first year the annual fee will be \$1. Dr. David F. Weeks is the collecting agent among the physicians and Dr. James I. Woolverton among the dentists.

**Physicians Commend Camden Board.**—The Medico-Surgical Society, at a recent meeting, in addition to commendatory remarks by the members on the action of the Board of Health for its prompt action in the smallpox cases, placed itself upon record by passing the following resolutions:

*Resolved*, That it is the consensus of opinion of this Society that the Board of Health of Camden City be commended for its prompt and efficient action in causing rigid quarantine, thus preventing a widespread epidemic of smallpox in our city; further, that the Board of Health be urged to continue the order of vaccination among all those who have not been successfully vaccinated; further, that it is the opinion of this Society that tetanus has no relation to vaccination, but is positively due to negligence on the part of those vaccinated or their parents in not having proper antiseptic care taken of their vaccination wounds, thus jeopardizing life by infection or accidental contamination; further, it is positively known to this Society, that all the cases sent to the new smallpox hospital since the beginning of the present epidemic were unvaccinated.

#### NEW YORK.

##### New York City.

**Dr. Paul F. Munde**, the well-known gynecologist, is very ill at his home in New York City.

**Pension to Physician's Family.**—The Board of Health has voted a pension of \$300 to the widow of Dr. Charles H. G. Steinsieck, who died recently after having been a member of the vaccinating corps for seven years.

**Dr. John E. Anderson**, who was sent to England, in the interest of the U. S. Marine-Hospital Service, to study the bubonic plague, has just returned to this country, and will make a detailed report to Surgeon-General Wyman.

**Physician to the Shah.**—Word has reached this city that Dr. M. Elezarian Randolph, a member of the New York County Medical Association, who left this city a few months ago for a short sojourn in Persia, is now at Teheran and has been appointed the personal physician of the Shah.

**The New York School of Clinical Medicine**, 348 West Forty-second Street, will begin the winter series of evening lectures on January 7. These lectures are quite independent from the regular courses of instruction. All members of the medical profession are welcome. The lectures will be given every Tuesday evening up to and including March 4.

**"Dr." Julius A. Ward**, who recently brought suit to recover \$90 which he alleged were due him for treatment of the wife of a lawyer, lost his suit, the Court holding that he is not a physician and is not entitled to collect a medical fee. He is a somatopath, and by virtue of his degree of D.D. uses the title of doctor in connection with his practice of the healing art. This verdict has encouraged the County Medical Society to prosecute him for illegally practicing medicine.

**Physician at the Head of the Street Cleaning Department.**—Mayor-Elect Low has selected to fill the very difficult, though highly important, position of street cleaning commissioner, Dr. John McGaw Woodbury, who served for a time as sanitary inspector of the Island of Porto Rico, and organized the first Board of Health of Ponce. After the war he was sent abroad by the United States Government, and there studied the systems of drainage and the methods of disposal of sewage and garbage and other refuse in Berlin, Frankfurt and Paris.

**Reorganization of the Health Department.**—The charter of the city has made some radical changes in this department, which will go into effect on the first of the new year. At the

present time, it consists of the president and two medical commissioners. The new board will consist of only three members, viz.: The health commissioner, who shall be the president, the health officer of the Port and the police commissioner. Mayor-Elect Low has announced the appointment of Dr. Ernest J. Lederle, the present chemist of the department, as the new health commissioner. Dr. Lederle, who is a doctor of philosophy and not a physician, is a graduate in chemistry from Columbia University. It is understood that Dr. Herman M. Biggs, at present the chief bacteriologist of the department, will be given charge of all the medical work of the department, under the title of medical officer, but the exact duties of this office have not yet been determined.

**Organized Medical Defense.**—The New York County Medical Association at a meeting held December 14 last, added a branch for the defense of its members against malpractice suits. This Association has employed a lawyer by the year, who in addition to representing it in all suits and threats against its members, will prosecute illegal practitioners and represent the Association in other ways. A committee previously appointed reported the following plan which was adopted:

1. The Executive Committee shall, upon request and compliance with the conditions hereinafter provided, assume the defense of suits for alleged malpractice brought against members of this Association.

2. The Executive Committee shall not undertake the defense of any suit based upon acts prior to the qualification of the accused as a member of the Association.

3. A member desiring to avail himself of the provisions of this Article shall make application to the Executive Committee through the secretary, shall sign a contract renouncing his own and vesting in the Executive Committee sole authority to conduct the defense of said suit or to settle by compromise, and shall make such other agreements as the Executive Committee may require.

4. The Executive Committee shall thereupon contract with said applicant to take full charge of said suit, to furnish all necessary legal services, to pay all necessary expenses and not to compromise said suit without consent of the accused, but the Executive Committee shall not obligate the Association to the payment of any damages awarded by decree of court or upon compromise.

##### Buffalo.

**Death-Rate.**—The health report for November of the Department of Health shows an annual death-rate of 14.44 per 1000 per annum.

**Visiting Days Suspended.**—The usual visiting days of the Buffalo State Hospital have been temporarily suspended because of a fear of introducing smallpox.

**The Smallpox Situation.**—The smallpox condition is much improved. There have been but two deaths and the cases are so mild that it is difficult to impress those affected (who are Polish and ignorant) that it is essential to have a rigid quarantine. During November, 13,792 children were vaccinated in the public schools.

**Magnetic Healers Assailed.**—Dr. J. B. Coakley, chairman of the board of censors of the Erie County Medical Society, commenced criminal action against an aggregation of magnetic healers calling themselves "Antonius, the Wonderful Boy Healer, and his staff." A hearing was given them in the police court, and the prosecution showed that their claims of wonderful cures were inventions, and that they took exorbitant fees from their dupes. They were held to the higher court for practicing medicine without a state license.

#### PENNSYLVANIA.

**Hospital at Saltsburg.**—A new four-story hospital building is to be erected at Saltsburg for the Clear Springs Sanatorium. It will accommodate 50 patients and will cost about \$30,000.

**Emergency Hospital Ready.**—The Emergency Hospital on Sprogel Heights, Pottstown, was completed and turned over to the Board of Health, December 20. It is a wooden building of one story, 45 by 16 feet. It has a ward, kitchen and nurses' room.

**Compulsory Vaccination Urged.**—The Columbia County Medical Society at its meeting in Bloomsburg, December 20, adopted resolutions calling the attention of school boards and all persons interested to the act of June 18, 1895, regarding compulsory vaccination and urging compliance with its provisions.

**Emergency Hospitals in Mines.**—Emergency hospitals have been placed in the Delaware, Lackawanna and Western Company's mines, in compliance with the act of the legislature providing for their equipment before January 1. Rooms have been fitted at each of the company's mines with every appliance necessary to save the lives of injured mine workers. Dr. Wainwright, chief of staff at the Moses Taylor Hospital, Scranton, has instructed mine foremen in first-aid for the wounded.

### Philadelphia.

**Pocono for Phthisis.**—Dr. J. E. Rothrock, State Commissioner of Forestry, believes that he has found a highly favorable climate for consumptives in the Pocono Mountains near Stroudsburg.

**Appropriation for Consumptive Pavilion.**—In the Finance Committee of Council's report recently made, \$80,000 is allowed for the construction of a pavilion for consumptives at the Philadelphia Hospital (Blockley).

**Bone Library.**—The Wistar Institute of the University of Pennsylvania is said to be the sole possessor of a "Bone Library." It contains the skeletons of almost every known animal. Each skeleton is dislocated and the bones are catalogued. Thus every bone may be studied separately in its proper class. A late addition is that of skeletons of three European apes, probably the only ones in America.

**Smallpox Outlook.**—For the week ended December 21, 76 new cases of smallpox were reported, deaths 10. The general outlook regarding the disease is hopeful, but dangerous foci for its spread still exist. One was recently discovered in which a family, including eight children, had had the disease for a month, but had concealed the fact. When a physician was at last called three of the children were in a critical condition, one dying within a few hours. The patients were speedily removed to the Municipal Hospital and the buildings for a considerable distance from the infected house were fumigated by order of the Chief of the Bureau of Health.

**Blockley Additions Blocked.**—The new additions to the Philadelphia Hospital, for which excavation has already begun, were to be erected on a triangular plot of ground adjacent to the University buildings. As this location interfered with the proposed extension of the Institute of Archeology, representatives from the university appealed to the Board of Charities and Correction asking that work on the hospital buildings be discontinued. The latter, thereupon, adopted a resolution affirming that, since there is no other available site and since the contract for the buildings has been let and work already begun, it is deemed inexpedient to make any change in the plans proposed and the site selected. The contest may be carried to the courts for settlement.

### DOMESTIC.

**Plague in Hawaii.**—A Chinaman died November 13 at Honolulu of the bubonic plague. Two deaths occurred from plague a week previously on the Island of Kauai.

**No Yellow Fever in Porto Rico.**—Dr. W. F. Smith, secretary of the Superior Board of Health, in contradiction to the statement of a Spanish newspaper, states that "no deaths from yellow fever have occurred in Porto Rico during the past three years, and no cases have been known during the past year."

**The American Society of Naturalists and Affiliated Societies** met at the University of Chicago, December 30 to January 2. This body consists of the following societies: The American Morphological Society, the Association of American Anatomists, the American Physiological Society, the American Psychological Society, The Western Philosophical Society, and the Society of American Bacteriologists. The meetings were all well attended and proved to be the most successful of the sessions ever held. We expect to have something to say of some of these societies next week.

**Hawaiian Physicians Must Understand English.**—Hereafter only physicians who are able to speak the English language will be given certificates allowing them to practice medicine in the Hawaiian Territory. The resolution to that effect was adopted by the Board of Health November 27 only after an animated discussion between the lay and the medical members, in which the former insisted that a knowledge of the English language was not a necessary adjunct to the learning of a medical practitioner. The physicians were in the majority at the meeting, however, and the new rule providing that examinations in the future be held only in the English language was adopted by a vote of three to two.

### CANADA.

**Montreal Medico-Chirurgical Society.**—At the last regular meeting of this society the following officers were elected for the current year: President, Dr. George E. Armstrong; first vice-president, Dr. H. S. Birkett; secretary, Dr. Alfred T. Bazin; treasurer, Dr. Jack; trustees, Drs. Perrigo, G. A. Brown and F. J. Shephard.

**Ontario Medical Library Association.**—The following gentlemen have been elected officers for the year 1902: President, Dr. J. F. W. Ross; vice-presidents, Drs. R. A. Reeve, A. A. Macdonald, and W. J. Greig; secretary, Dr. H. J. Hamilton; treasurer, Dr. H. A. Bruce; curator, Dr. N. A. Powell; assistant curator, Dr. W. J. Wilson.

**Smallpox in Ontario.**—The disease is still rapidly spreading throughout the province, a dozen or more cases being reported to the Provincial Board of Health, daily. Since the first of October there have been 580 cases reported with only three deaths. There are now over 433 cases in the province. Ottawa has over 90 cases while Toronto has two.

**Physician Violates Hygienic Regulations.**—The Province of Quebec Board of Health has entered action against a physician of St. Marcel, Richelieu County, for violating the smallpox regulations. He was himself attacked by smallpox and still went even into the neighboring parish of Bagot County, without reporting his case to the health authorities of either county.

**Appointments.**—Dr. C. D. Parfitt, late of the Johns Hopkins Hospital, has been appointed resident physician at the Gravenhurst Sanitarium, Muskoka.—Dr. J. Alexander Hutchinson, Montreal, senior surgeon of the Grand Trunk Railway, has been appointed surgeon-in-chief of the Central Vermont.—Dr. W. H. Piersol, Toronto, has been appointed instructor in biology and histology at Toronto University.

**New Vaccination Order for Quebec.**—The Board of Health of the Province of Quebec has ordered every municipal council in that province to adopt, promulgate and cause to be obeyed, by-laws, to provide that two days after such by-laws come into force, any person who can not establish that he has been successfully vaccinated within seven years or unsuccessfully within six months, will be liable to a fine of \$5, with another dollar for each day of delay, if he does not become vaccinated at once.

**Quebec Doctors Must Pay Annual Assessment.**—Mr. Justice Dorian in the circuit court has just rendered a judgment of some interest to the medical profession in the province of Quebec, in the case of the College of Physicians and Surgeons against Dr. Auguste Bourbonnais, M. P., for Soulanges. According to the ruling of the judge a doctor must pay his annual assessment of \$2 to the governing body of the profession, or cease the practice of his profession. Judgment was rendered for the plaintiffs for \$24 with costs so the doctor must have been some twelve years in arrears.

**British Columbia Items.**—Vancouver is to erect a new hospital at a cost of \$100,000. The last annual report of the Victoria Royal Jubilee Hospital shows that there were 807 in-patients treated during the year and 154 out-patients. The receipts from all sources amounted to \$38,091, the amount received from pay patients being \$18,208.—The provincial Board of Health has issued special instructions to health officers and inspectors with regard to milk depots and dairies, and hereafter persons of uncleanly habits or afflicted with disease will be prohibited from dealing in or handling milk.

**Field Hospital for South Africa.**—The Imperial authorities have accepted the offer of a Field Hospital from Canada for service in South Africa. It will have no connection with the Third Contingent which will leave Halifax about the last of January, but will form a distinct unit by itself. Dr. A. N. Worthington of Sherbrooke, Que., will go in charge as surgeon-colonel, he having already served in South Africa with the Canadian Artillery. Dr. H. D. Johnson of Charlotte-town, P. E. I., will be lieutenant and Dr. Jones of Halifax, captain. Two other medical practitioners will accompany it, Drs. Roberts and H. E. Tremayne of Toronto.

**Muskoka Cottage Sanitarium.**—The medical superintendent, Dr. J. H. Elliott, has made his report for the past hospital year. Of the 99 cases treated during the year, 15 have been discharged apparently cured, and 29 with the disease arrested. Of the latter number, 14 gave promise of cure had their financial condition permitted a longer sojourn in the hospital. It is considered highly satisfactory that in 44 out of 99 cases the disease had undergone more or less complete subsidence. The average gain in weight has been 13 pounds, and there has been an average gain in those remaining over three months of 14½ pounds. The cases were classified on admission as follows: Incipient, 24; advanced, 43; far advanced, 32.

### FOREIGN.

**Pellagra Congress.**—The second National Italian Antipellagra Congress will meet at Bologna next May.

**Royal Commission on Tuberculosis.**—This committee has accepted two farms in Essex offered for experimental purposes.

**Smallpox in London.**—The smallpox epidemic is steadily increasing. On December 28 there were 637 cases under treatment.

**Dr. Samuel Smiles**, of London, author of the "Self Help" series, celebrated his 90th birthday on December 23. His last book, "A Publisher and His Friends," netted him \$10,000, which he divided among his children as a Christmas gift.

**Certificate of Physical and Mental Capacity in Marriage.**—The Bohemian Medical Society has had introduced into the Austro-Hungarian Reichstag a bill to regulate marriage by making a certificate of physical and mental capacity obligatory for candidates for matrimony.

**Italian in Medical Congress.**—Baccelli has declined an invitation to address the coming International Medical Congress at Madrid, on the ground that Italian is not recognized as one of the official languages. He appeals to his compatriots to hold aloof also from the Congress on this account.

**Death of Professor Loehlein.**—Germany has lost one of her most prominent and public-spirited gynecologists in Hermann Löhlein of Giessen. Science owes to him the introduction and scientific foundation of pelvic measurements, and innumerable contributions to the literature. He has been publishing regularly since 1890 some of his lectures, etc., under the title "Questions of the Day in Gynecology."

**The Centennial of the "Internat" in France.**—The internes of Paris have completed their arrangements for the celebration of the centennial of the founding of the system of internes in hospitals. It will occur during several days in the first week of April and will include a ceremonial assembly, banquet and dedication of the monument in the inner court of the Hotel Dieu to the memory of the internes who died victims of their professional devotion, of which many touching stories are told.

**Dr. A. Campbell Clark**, a leading British alienist, died, November 28, from influenza with visceral complications. He was well known from his contributions to psychiatric literature and especially as an expert on asylum management and construction. He was a pioneer in his country in the movement for the scientific training of attendants on the insane and was one of the authors of a practical treatise on the subject. His best-known work is "A Clinical Manual of Mental Diseases" published in 1897. His professional work was almost entirely in asylums, he having been connected with them since his graduation from the University of Edinburgh in 1886.

**Behring Proclaims the Successful Immunization of Cattle Against Tuberculosis.**—In his recent address at the Stockholm Academy of Sciences as the recipient of one of the Nobel prizes, Behring announced the success of his efforts to immunize cattle against tuberculosis. His method is similar to Pasteur's immunization of sheep against anthrax, that is, the injection of attenuated tubercle bacilli from man. The next step is to determine the minimal effective amount and reduce the expenses of this protective measure. He stated that he intends to devote the Nobel prize to this end. He announced that he considers himself justified in asserting even now, that the immunization of cattle against tuberculosis is an established fact.

## Correspondence.

### Hydrophobia Rabies and Dr. Dulles.

PHILADELPHIA, Dec. 17, 1901.

*To the Editor:*—In THE JOURNAL of Dec. 7, 1901, I note the following item: "*Rabies.*"—Salmon's paper is a discussion and convincing analysis of the statistics, combating the statements of Dulles and others who argue that hydrophobia does not exist." Although I might despair of correcting the misapprehensions of persons who could attribute to me such an absurdity after reading any of my papers on the subject of rabies or hydrophobia, I will state, for the information of those who have not seen any of these papers and who might be excused for misunderstanding me, that I have never denied the existence of hydrophobia. I have repeatedly asserted in public and in print the position I have for years held, namely

that the word "hydrophobia" should, for the present, be used as we use the word "convulsions," to describe a condition but without prejudice as to its cause. I published nearly eighteen years ago a paper in which I gave an account of the occurrence of this condition in more than thirty diseases, and I think it reasonable to ask that the profession would make itself acquainted with the facts of this nature which are within its reach before giving itself up to a theory, the adoption of which is about as bad, in my opinion, as giving oneself up to an exclusive dogma in practice, in that it fills its votaries with an unwarranted content with their present attainments and shuts them off from those open-minded and logical methods of investigation which alone can furnish the proper ground for a just appreciation of the work of others.

My idea is that we must first eliminate from our equation the large number of cases presenting the clinical picture of hydrophobia and afterwards study in a properly critical way what is left, and then we may find a definition of the word that will stand. At present the subject is obscured by much that is irrelevant, and certain disputants do not seem (*me judice*) to appreciate this sufficiently.

With due deference to those who regard my views as unsound, after twenty years of striving to learn the truth I am of the conviction that clinical hydrophobia in man and the disease in animals called rabies and judged by its inoculability in the un-natural way taught by Pasteur are not the same specifically. Of the former there are many causes besides the bites of animals suffering with rabies.

To the scientific arguments in Salmon's valuable and forceful paper I am now preparing a reply; for I think it contains some statements that would be better for decision of the premises on which they are founded. C. W. DULLES, M.D.

### Car Sanitation.

INDIANAPOLIS, Dec. 17, 1901.

*To the Editor:*—The dispatches announce that a new palace car company with a capital of \$5,000,000 has been organized in New York. This company will, perforce, build new cars, and it seems to me now is the time for those members of the medical profession who believe in helping their fellowmen to emphatically demand proper ventilation, without draughts. Surely such a thing is possible. It is to lack of ventilation, to which must be attributed the coughs, catarrhs, colds and cases of pneumonia and grip which so frequently are acquired on sleeping cars. White blankets should also be furnished, so when they are soiled and dirty, the passenger, who is paying large dividend producing prices, will know it. The traveling public is very particular in regard to having white, clean sheets and pillow cases, but is singularly silent about the colored blankets which so frequently emit musty and bodily odors.

Then would it not also be a convenience and a distinct advanced step in car sanitation to adopt Dr. Fulton's suggestion and have special sinks in the toilet rooms over which the ablutions of the mouth could be performed? At present, the washings of the mouth and teeth and the voidance of oral excrement, during the process, are discharged into the wash basins. It would be a good thing also to do away with carpets and have rugs on rubber tiled floors. Rubber tiling is as beautiful as vitrified tile; it is impervious, furnishes a sure footing and will withstand the motion of the cars. Rugs could be taken out at any terminal and others put in which had been dusted, steamed and sterilized. What an improvement this would be over the dirt-stiffened, spit-soaked carpets now so much in evidence! There seems to be no substitute for plush. Leather is too cold and slippery, and cane is too hard, cold and also slippery. The best way to handle this matter would be to have the backs and bottoms of the seats removable; then they could be taken out, dusted with the air blast, and sterilized. How comfortable it would be to know that the plush of your sleeping-car section was even occasionally thoroughly dusted and sterilized.

J. N. HURTY, M.D.

Secretary Indiana State Board of Health.

**Feeling the Nurse.**

BISMARCK, N. D., Dec. 20, 1901.

*To the Editor:*—In THE JOURNAL of the 14th inst. you comment on what you evidently consider an undesirable innovation in medical practice in England, viz., the dividing of the fee, in obstetric cases, with the nurse. This is not by any means a new custom in England, nor is it attended by the evil results that might be anticipated; and if it could be carried out in some localities in this country many a practitioner would be glad to practice a system that would save any "booking" of obstetric fees.

Over twenty years ago I was an assistant to a general practitioner in the east end of London, and a large part of his practice consisted of obstetric work, in a rather poor part of the city. The usual fee for such cases was one guinea, 21 shillings, and it was the custom to hand the odd shilling to the nurse. On the physician's last visit to the case, usually on the tenth day after the confinement, the fee was handed to him *by the nurse* and he politely passed over the shilling. Even with patients who had accounts standing for other attendance it was customary to pay cash for labor cases and it was to the nurse's interest to keep patients posted in this respect because in case of failure she lost her "tip."

As the practice was common with all physicians it was no benefit to any particular one and was only a part of the almost universal system of "tipping" that prevails in most European countries.

F. R. SMITH, M.D.

**Appendectomy—Surgical History.**

CINCINNATI, Dec. 16, 1901.

*To the Editor:*—I thank Dr. Frank Woodbury for calling my attention (THE JOURNAL, page 1620, Dec. 14, 1901) to Dr. Thomas G. Morton's case of appendectomy—April 23, 1887.

In my investigation Dr. Morton's case was overlooked. It is to be regretted. In this paper, as in all I present, honest criticism is coveted.

In the question of priority, I will say that Dr. Stemen of Fort Wayne, Ind., stated to me yesterday that he made a diagnosis of appendicitis, performed a celiotomy and removed the appendix during 1884.

I am indeed sorry that these facts did not appear in my paper.

Very truly,

B. MERRILL RICKETTS, M.D.

**Registration of Non-Resident Physicians Discontinued.**

BOWLING GREEN, KY., Dec. 17, 1901.

*To the Editor:*—Since your recent publication giving the requirements of the various states for licenses to practice medicine this Board has been over-run with applications from all over the Union from physicians who do not expect to practice medicine in Kentucky at present, if ever. Our law makes no provision for the registration of non-resident physicians. For a time those living near our borders in adjoining states were permitted to register, but, upon the advice of our counsel, even this has been discontinued.

Very respectfully,

J. N. McCORMACK, M.D.,

Secretary State Board of Health.

**Married.**

HUGH J. DEATH, M.D., to Miss May Thirkield, both of Franklin, Ohio, December 11.

E. T. BOYD, M.D., to Miss Sadie E. Edwards, both of Leadville, Colo., December 12.

ALBERT B. DEERING, M.D., Boone, Iowa, to Miss Jean Miller, Cheyenne, Wyo., December 18.

JAMES C. CARTER, M.D., to Miss Corinne Greer, both of Knoxville, Tenn., December 17.

J. F. TAYLOR, M.D., Briggs, Texas, to Miss Ola Fowler, Meridian, Texas, December 22.

VIRGIL L. TUPPER, M.D., to Miss Mary H. Cranage, both of Bay City, Mich., December 12.

JOHN CASSEL BUCKWALTER, M.D., to Miss Edna Wright, both of St. Louis, December 23.

GEORGE B. NORBERG, M.D., to Miss Janette Lockwood, both of Kansas City, Mo., December 11.

GEORGE E. MARTIN, M.D., Anna, Ohio, to Miss Anna Williamson of Sidney, Ohio, December 17.

CHARLES C. MOFFETT, M.D., Lorain, Ohio, to Miss Elsie Long, of Elyria, Ohio, December 19.

WILLIAM E. SAWYER, M.D., St. Louis, Mo., to Miss Irene Borders of Sparta, Ill., December 18.

DAVID CHARLES STRONG, M.D., Wichita, Kan., to Miss Mary Alice Glenn of Chicago, December 25.

G. C. TRUEHART TAYLOR, M.D., to Miss Bernice Stephenson, at Huntington, W. Va., December 11.

JOHN R. PIPES, M.D., Avon, Ohio, to Miss Carrie K. Williams of Cleveland, Ohio, December 11.

CHARLES A. ELLIS, M.D., Sherman, N. Y., to Miss Alice Miles, at Buffalo, N. Y., December 15.

JOHN WILLIAM COE, M.D., New York City, to Miss Mamie Clark of Lexington, Ky., December 25.

AUGUST FREDERICK LEMKE, M.D., to Miss Jessie Josephine Stewart, both of Chicago, December 21.

W. J. LONEGAN, M.D., Princeton, Wis., to Miss Anna Hafer of Marshfield, Wis., November 8.

ROBERT B. PEARSON, M.D., to Miss Lucelia W. Lippincott, both of Bonaparte, Iowa, December 11.

PAUL JOSEPH GELPI, M.D., to Miss Marie Annette Hincks, both of New Orleans, La., December 26.

LOUIS F. WEAVER, M.D., Syracuse, N. Y., to Miss Emma A. Hubel of Woodstock, Ont., December 16.

LYNN HARRISON, M.D., Butler, Ind., to Miss Effie A. Baldwin of Conandaigna, Mich., December 11.

J. J. YATES, M.D., Roberson Fork, Tenn., to Miss Anna Pickens of Mooresville, Tenn., December 9.

JAMES F. KENDRICK, M.D., West Charleston, Vt., to Miss Rose Sherburne of Glover, Vt., December 4.

J. EDGAR WHEAT, M.D., Fernando, Cal., to Miss Luna Murphy of East Los Angeles, Cal., December 4.

ESTELLE H. HENDERSON, M.D., Newbern, Va., to Miss Loula Wallace of Pulaski City, Va., November 9.

OTIS W. MILLER, M.D., to Miss Helen M. Sahn, both of St. Louis, Mo., at Clayton, Mo., December 23.

HUGH A. BARBEE, M.D., Point Pleasant, Pa., to Miss Mary Esther Byers of Pittsburg, Pa., December 18.

ANDREW HARSCHER, M.D., to Miss Louise Ludwig, both of St. Louis, Mo., at Clayton, Mo., December 18.

HUGH LIVINGSTON, M.D., Hopkinton, Iowa, to Miss Hattie Stewart of New Hartford, Iowa, December 17.

SAMUEL E. LLOYD, M.D., to Miss Regina Bowen, both of Towson, Baltimore County, Md., December 11.

ROSCOE A. CARTER, M.D., Lynden Center, Vt., to Miss Grace Mae Densmore of St. Johnsbury, Vt., December 10.

CHARLES R. GRAHAM, M.D., Tullahoma, Tenn., to Miss Minnie Lee Jacobs of Murfreesboro, Tenn., December 11.

JOHN BRADFORD WATERS, M.D., Hartford, Conn., to Miss Edith Mills Decker of New York City, December 18.

W. C. MEHLARG, M.D., Grayton, Ala., to Miss Zula, daughter of Dr. Philip H. Brothers, of Zula, Ala., December 5.

WILLIAM CARVER, M.D., son of Dr. Joseph B. Carver, to Miss Lillian Bacon, both of Fort Scott, Kan., December 10.

HENRY HARRINGTON JANEWAY, M.D., New Brunswick, N. J., to Miss Elizabeth, daughter of Dr. L. Duncan Bulkley, New York City, December 23.

**Deaths and Obituaries.**

**George Bayles, M.D.** College of Physicians and Surgeons, New York City, 1859, died at his home in Orange, N. J., December 20, from heart failure, after an illness of two days, aged 65. On the outbreak of the Civil war Dr. Bayles offered his services to the government and was appointed assistant surgeon. He served throughout the war, and at its close held the rank of major and surgeon. He was made sanitary inspector of Lexington, Ky., and later inspector of children's diseases for the New York Board of Health. In 1879 he moved to Orange, N. J. He became a member of the New York Academy of Medicine in 1867, was a member of the American Medical Association, Orange Mountain Medical Society, a member and ex-president of the Essex District Medical Society and a member of the New Jersey State Medical Society. During the Spanish-American war he served as post surgeon at Fort Hancock.

**Donald S. Campbell, M.D.** University of Michigan, 1877, a prominent physician and specialist on diseases of the ear, nose, throat and lungs, died at the Detroit Sanatorium, December 17, from typhoid fever, after an illness of three weeks, aged 44. After his graduation, Dr. Campbell studied four years in Scotland and England, and in 1883 was a member of the Greeley relief expedition to the Arctic. In 1885 he settled in Detroit. He was a member of the Detroit Medical Society, Michigan State Medical Society, American Electro-Therapeutic Association and of the American Medical Association.

**Rush S. Huidekoper, M.D.** University of Pennsylvania, Philadelphia, 1877, died at Philadelphia, December 17, after an operation for inflammatory chest disease, aged 47. He gained prominence by reason of his successful fight in the United States Senate for an organized veterinary service for the United States Army. In 1898 he was appointed chief surgeon of the First Army Corps with the rank of lieutenant-colonel, was stationed at Chickamauga, and was prominent in the "embalmed" beef investigation.

**J. Milton Hadley, M.D.** University of Pennsylvania, Philadelphia, 1860, who served throughout the Civil war as a surgeon on the Confederate side, and thereafter practiced two years in Oakes, Orange County, N. C. He moved to La Grange in 1867 and died at his home in the latter place, December 13, aged 65. He was one of the organizers of the Lenoir County Medical Association, and at one time its president, and a member and vice-president of the State Medical Society.

**Richard L. Butt, M.D.** New York University, 1846, died at his home in Midway, Ala., December 18, after an illness of 18 months, aged 77. He served as surgeon during the Civil war on the staffs of Generals Jackson, Van Dorn and Forest. At the close of the war he practiced in Memphis, Tenn., but in 1875 moved to Midway. He had been a member of the national and state medical associations, and was once president of the Bullock County Medical Society.

**Caleb Du Hadway, M.D.** Missouri Medical College, St. Louis, Mo., 1867, who had practiced in Jersey County, Ill., ever since his graduation, died at his home in Jerseyville, December 21, from paralysis, aged 68. He was a surgeon in the Confederate service for two years, a member and some time president of the Jersey County Medical Society, and is credited with being the discoverer of the anesthetic properties of carbolic acid.

**William E. Bowman, M.D.** Rush Medical College, Chicago, 1886, a prominent physician of Elkhart, Ind., was instantly killed, December 18. He was driving home from a professional call at Bremen, Ind., and while crossing the tracks of the Lake Shore road at Mishawaka, his buggy was struck by the fast mail and he and his driver instantly killed. Dr. Bowman had resided in Elkhart for fifteen years. He was 38 years old.

**Fred James Perry, M.D.** Rush Medical College, Chicago, 1892, one of the most prominent physicians of Fort Atkinson, Wis., died at St. Joseph's Hospital, Milwaukee, December 19, from appendicitis, for which an operation was performed a week previous. He was a member of the Central District and State Medical Societies and of the American Medical Association. He was 36 years of age.

**Jesse Groome Shoemaker, M.D.** University of Pennsylvania, Philadelphia, 1886, prominent as a citizen and practitioner of Phoenixville, Pa., died at his home in that place, December 14, after a lingering illness, aged 35. He was president of the Phoenixville Hospital and a member of the State Board of Health and the Chester County Medical Society.

**Nelson E. Jones, M.D.** Western Reserve University, Cleveland, 1846, the oldest practitioner of Pickaway County, Ohio, died at his home in Circleville, from uremia after a long illness, December 15, aged 80. He served as surgeon of the Board of Enrollment for the Twelfth Ohio District through the Civil War and thereafter served on the pension examining board.

**Salmon Hudson, M.D.** Starling Medical College, Columbus, Ohio, 1862, one of the oldest and best known physicians of Medina County, died at his home in Medina, Ohio, December 11, from paralysis, after an illness of three years, aged 81.

During the Civil war he served as assistant surgeon in the 23d and 11th Ohio Volunteer Infantry.

**James R. Deane, M.D.** Medical School of Maine, Bowdoin College, Brunswick, 1860, assistant surgeon in the Navy during the Civil war and for a quarter of a century an esteemed practitioner of Newton Highlands, Mass., died December 6 at his home, after a protracted illness, aged 68. He was a member of the Massachusetts Medical Society.

**William Hilleary Johnson, M.D.** University of Maryland, Baltimore, 1849, died at his home in Adamstown, Frederick County, Md., after a long illness, December 13, aged 74. He was a surgeon in the Confederate service during the Civil war, and since its close had resided and practiced in Adamstown until his retirement in 1899.

**James Sawyer, M.D.** Medical School of Maine, Brunswick, 1846, formerly a member of the state legislature, from which he resigned to serve as surgeon throughout the Civil war, and thereafter a practitioner in Biddeford, Maine, died at his home in that place after an illness of two days, from paralysis, December 18, aged 79.

**De Witt J. Jordan, M.D.** Kentucky School of Medicine, Louisville, 1892, who recently moved from Indianapolis to Anderson, Ind., was frozen to death in a snowstorm, near Rosedale, Ind., while making a professional call, December 13. He was 30 years old and was a member of the American Medical Association.

**James W. Smith, M.D.** Berkshire Medical College, Pittsfield, Mass., 1847, the oldest practicing physician in Ohio, died at his home in Wellington, December 10, from paralysis, after an illness of ten days, aged 80. He served with distinction throughout the Civil war, and at its close held the rank of colonel.

**John C. Mayfield, M.D.** Tulane University, New Orleans, La., 1874, state quarantine officer at Galveston, Texas, for the past five years, and previously a practitioner at Velasco, Columbia and Richmond in that state, died at San Antonio, December 19, from kidney disease, after a protracted illness, aged 51.

**Peter Drayer, M.D.** Starling Medical College, Columbus, Ohio, 1867, one of the most prominent and oldest physicians of Eastern Indiana, for 35 years a resident of Hartford City, died from consumption at his home in that city, December 20, aged 61. He was a member of the American Medical Association.

**James Henry Munn, M.D.** Louisville (Ky.) Medical College, 1887, one of the most prominent physicians of Florence County, S. C., and a member of the American Medical Association, died at his home in Hyman, December 7, after an illness of several weeks, from acute pulmonic phthisis, aged 38.

**John Stark, M.D.** University of Glasgow, Scotland, 1863, a widely-known physician of Kansas City, Mo., and during the Civil war a surgeon on the staff of Gen. George B. McClellan, died at his home in Kansas City, December 17, from pneumonia after an illness of eight days, aged 60.

**Daniel McFarlane, M.D.** Edinburgh, Scotland, 1864, prominent and beloved as a practitioner for nearly 30 years in Keola, Iowa, died while attending a patient, near that town, December 10, from heart disease, aged 60. He was a member of the American Medical Association.

**James R. Deane, M.D.** Medical School of Maine, Bowdoin College, Brunswick, 1860, assistant surgeon in the Navy during the Civil war and for a quarter of a century an esteemed practitioner of Newton Highlands, Mass., died December 6 at his home, after a short illness.

**Robert W. Tate, M.D.** Long Island College Hospital, Brooklyn, for thirteen years a practitioner in Greensboro, N. C., and once vice-president of the North Carolina Medical Society, died at his home in Chadbourn, N. C., November 29.

**James Kent Harper Jacobs, M.D.** University of Maryland, Baltimore, 1897, died suddenly at Centreville, Queen Ann's County, Md., December 18, aged 45. He practiced at Kennedysville, Kent County, until 1897, when he removed to Centreville.

**Alexander Jackson, M.D.** Harvard University Medical School, Boston, 1843, a prominent physician of Plymouth,

Mass., from his graduation until his retirement in 1890, died at the home of his son in Boston, December 12, aged 82.

**Benjamin F. Kibler, M.D.** University of Maryland, Baltimore, 1880, died at his residence in Dayton, Rockingham County, Va., from consumption, after a long illness, December 8. He had practiced in Dayton for about fifteen years.

**William J. McConkey, M.D.** University of Glasgow, Scotland, 1854, who had practiced thirty years in Mapleton, Ohio, and then moved to Canton, died at his home in that city from cancer of the stomach, December 5, aged 70.

**George Bridges Henshaw, M.D.** Harvard University, Boston, 1894, formerly bacteriologist to the Cambridge Board of Health, and a practicing physician of Cambridge, Mass., died at New Rochelle, N. Y., December 19.

**Nicholas J. Wilson, M.D.** University of Nashville, Tenn., 1860, died at his home in Byhalla, Miss., December 10, after a brief illness, aged 67. He had practiced medicine in and around Byhalla for more than forty years.

**Lucius L. Wakefield, M.D.** Rush Medical College, Chicago, 1863, one of the best-known physicians of Central Illinois, died at his home in Sumnum, December 23, aged 66. He leaves an estate valued at \$100,000.

**Ephraim F. Leake, M.D.** University of Pennsylvania, Philadelphia, 1845, who had practiced medicine in Frankford, Philadelphia, since 1847, died at his home in that city, December 13, after a short illness, aged 80.

**Levi M. Dixon, M.D.** Missouri Medical College, St. Louis, 1867, for many years a practitioner in Nevada and Vernon County, Mo., died from tuberculosis at his home in Nevada, December 11, after a prolonged illness.

**Robert W. Murphy, M.D.** Bellevue Hospital Medical College, New York, 1871, a California pioneer, and for many years a practitioner in San Francisco, Cal., died at his home in that city, December 7, aged 80.

**Frederick J. Murdock, M.D.** Kansas City Medical College, 1891, a practitioner of Kansas City, Mo., died December 23, at St. Joseph's Hospital, Kansas City, after an illness of one week, from meningitis, aged 45.

**Thomas Waterman, M.D.** Harvard Medical School, Boston, 1868, known as an expert on insanity, died at his home in Boston, December 14, from heart failure following an operation on the throat, aged 59.

**John W. Runcie, M.D.** Jefferson Medical College, 1871, an old and respected physician and citizen of Fort Branch, Ind., died at his home in that place, December 17, from cerebral hemorrhage, aged 74.

**Peter Mehring, M.D.** Washington University, St. Louis, Mo., 1879, for twenty years a practitioner of Portage des Sioux, Mo., died, December 19, at his home in that place from pneumonia, aged 59.

**Everett J. Whitehead, M.D.** University of Michigan, Ann Arbor, 1890, of Columbus, Ohio, died at Kaneth, Va., where he had gone to nurse a sick brother, from pneumonia, December 17, aged 42.

**Wiley Elias Gainey, M.D.** Grant University, Chattanooga, Tenn., 1893, an esteemed physician of Mayo, Fla., died at his home in that place from bronchitis after a long illness, December 15.

**John H. Bell, M.D.** New York University, 1865, one of the best-known physicians of Southwest Michigan, and once mayor of Benton Harbor, Mich., died at his home in that city, December 29.

**Elias P. Ilff, M.D.** Long Island College Hospital, Brooklyn, 1877, a successful practitioner of Newark, N. J., died at his home in Newark, N. J., December 22, after an illness extending over a year.

**Andrew Gilroy, M.D.** University of Vermont, Burlington, 1884, a practitioner of Jewett City, Conn., died at the home of his mother in Norwien, Conn., from consumption, December 12, aged 38.

**Conrad J. Crounse, M.D.** Albany Medical College, 1846, who had practiced in Clarksville, N. Y., for more than 45 years, died at his home in that place, December 12, aged 79.

**George W. Akard, M.D.** University of Tennessee, Nashville, 1888, a practitioner of Springtown, Parker County, Texas, died suddenly at Weatherford, Texas, December 19.

**C. H. Kermott, M.D.**, for the past twelve years agency physician at Fort Totten, N. D., died December 11, at his residence in Fort Totten, from pneumonia, aged 65.

**Orrin E. Miner, M.D.** New York University, 1859, the oldest physician in Noank, Conn., died at his home in that village, December 22, after a lingering illness.

**Alfred S. Wiley, M.D.** Dartmouth Medical College, Hanover, N. H., 1888, died from typhoid fever, at his home in Newton Highlands, Mass., December 20.

**Loretta J. Pettit Baird, M.D.** University of Minnesota, Minneapolis, 1894, died suddenly from embolism at her home in Rushmore, Minn., December 17.

**Hiram Leonard Ives, M.D.** Albany Medical College, died at the Samaritan Hospital, Troy, N. Y., December 17, from pleuro-pneumonia, aged 62.

**Green R. Price, M.D.** Grant University, Chattanooga, Tenn., 1894, died suddenly at his home in Waco, Ga., December 20, from heart disease.

**John B. Fella, M.D.**, Wurzburg, died at his home in Toledo, Ohio, after a lingering illness from bronchial phthisis, December 14, aged 67.

**Clinton S. Chase, M.D.** Castleton (Vt.) Medical College, 1854, died from pneumonia at his home in Detroit, December 15, aged 70.

**John F. Bigelow, M.D.** Rush Medical College, Chicago, 1882, died at Cook County Hospital, December 28, from pneumonia.

**George E. Dixon, M.D.** University of Vermont, Burlington, 1892, died at his home in Milton, Vt., December 20.

**William S. Barrickman, M.D.**, Fairfield, Ill., died at his home in that place, December 17.

## Book Notices.

THE PRINCIPLES OF PATHOLOGICAL HISTOLOGY. By Harvey R. Gaylord, M.D., and Ludwig Aschoff, M.D., with an introductory note by William H. Welch, M.D. Quarto, 354 pages, with 81 Engravings in the Text and 40 Plates. Cloth, \$7.50. Philadelphia and New York: Lea Brothers & Co.

The handsome volume before us is worthy of more than a casual review. The authors have prepared an atlas covering the ground of a good course in practical microscopic pathology of the special organs, accompanied by descriptive text. The volume is divided into three parts: 1. Microscopic Technique; 2. Pathological Histology of Organs; 3. The Principles of Optics and Photomicrography.

In Part I, there is a general introduction with regard to care in the use of the microscope. This is followed by a description of the methods for the manipulation of fresh material and later of the methods for the preparation of hardened material. The whole section on technique has been well done. The authors have been liberal with regard to the number of methods recommended, and while in a volume of this size and scope it is scarcely possible to include all, or even the good methods, yet very few of the better technical procedures will be found to be lacking. We should have been glad to have found more emphasis laid upon the use of the dissecting microscope—the hand-lens; to have seen mention made of Barden's freezing microtome; to have had Weigert's method of neuroglia staining described as well as Mallory's; to have seen the original Nissl method and Held's modification of it introduced, and to have had some attention paid to the very important work of Fischer on the fixation and staining of protoplasm. (It is mentioned in a foot-note only.)

The second part, which comprises almost three-quarters of the whole volume, is the part to which the reviewer's attention must be more particularly directed. Without preamble, the structure and pathologic alterations of heart muscle are taken up, and this is followed successively by similar treatment of the skeletal muscles, liver, kidney, pancreas, lung, mucous membranes, serous membranes, vascular system, lymph nodes, spleen, genital organs, tumors and blood. Just what has de-

terminated the order of presentation does not seem clear, as the arrangement of topics in the series scarcely corresponds to any of the ordinary sequences of description or consideration. Under each heading, a series of characteristic pathologic changes are considered by number, each number apparently corresponding to a section given out in the microscopic course. Thus, under heart muscle, we find specimens of the following lesions described: 1, fatty degeneration; 2, invasion of the heart muscle by fat cells; 3, parenchymatous degeneration (cloudy swelling); 4, brown atrophy; 5, abscess in the heart muscle; 6, myocarditis chronica fibrosa; 7, tuberculosis of the heart muscle; 8, fragmentation of the myocardium. Of these eight specimens described, five are illustrated by photomicrographs.

The treatment of the various topics is very much like that accorded them in the better courses in pathologic histology in this country and in Germany. The choice of subjects conforms very closely to that met with in such courses. We are not struck by any particularly new features, nor is one impressed by the absence of typical preparations usually described.

Each topic is preceded by a very brief epitome, dealing with the normal structure of the part—a feature which, it may be remembered, is characteristic of Orth's text-book. There is something to be said in favor of such an introduction, but much depends upon the way it is made. Now that we have such excellent text-books upon normal histology and microscopic anatomy, and now that in all good medical schools very fair courses upon the normal structure are given to students before they approach the subject of pathology, there no longer exists that need that previously obtained for a description of normal structures given in a text-book on pathology. The descriptions given in Orth's book were of particular value, because they emphasized especially those features of normal structure and of normal relations which were of unusual significance for the explanation of pathologic changes in the organ. No attempt, however, was made by Orth in his text-book to give a full description of normal structures. Indeed, his remarks were limited chiefly to hints with regard to the normal from the pathologist's view-point—hints at relations which the teacher of normal histology or microscopic anatomy, unless he were a pathologist, would be likely to overlook. Gaylord and Aschoff have, it seems to us, missed this point entirely. The descriptions they give of normal structure are brief general descriptions, such as might be given to the most elementary class in normal microscopic work. These descriptions are utterly inadequate for the medical student who is approaching modern pathology. They are sure to be criticised severely by students who have taken good courses on the microscopic structure of normal organs, and to insufficiently prepared students they can only be misleading for they will yield the impression that the normal descriptions here to be found are adequate as knowledge preliminary to the study of diseased organs. Some of these descriptions of normal structure are more unfortunate than others. The descriptions of the kidney, lung and bone marrow are very poor. In the remarks on the normal structure of the intestines, the solitary follicles are not distinguished from Peyer's patches; Auerbach's plexus is mentioned, but nothing is said of Meissner's; the astonishing remark is made, on p. 162, that "the mucosa of the small intestine is thrown into more or less regular transverse folds, the villi." In the description of the lymph gland, where lymph cord is intended, the authors use the expression "radiating structures of lymphocytes." In the description of the tracts of the central nervous system, we find the statement that "the anterior pyramidal tracts are composed of motor fibers from the ganglion cells of the anterior horns of the same or opposite side" (!) On page 214 the impression is given that Marchi's method and the Weigert-Pal method may be used indiscriminately for demonstrating degenerated tracts, nothing being said about the use of the two methods in different stages of degeneration.

The text of the descriptions of pathologic lesions themselves is better, and in general may be considered as brief but adequate. The descriptions of pathologic lesions in the lung are particularly good; the section on arteriosclerosis is also good. The specimens from the genital organs are well chosen, and,

as a rule, well described. The section on tumors is certainly one of the best parts of the book. The descriptions are modern, clear, and, so far as tested, accurate. Gaylord's views on the etiology of carcinoma are developed with reserve, and the bibliography is reviewed with a special reference to parasitic origin.

The section on the blood, written by Lyon, is exceptionally good. Seldom have we seen compressed into such narrow limits so many data on the pathology of the blood. On the other hand, the section on the nervous system is so fragmentary and so superficial that it would have been much better to have omitted it altogether. The description of the lesions in dysentery is also insufficient. The distinction between amebic and other forms is mentioned, but the characterization of the lesions in the different types has been overlooked. The same is true with regard to abscesses of the liver. The local reaction in so-called amebic abscesses is quite different from that to be met with in true abscess, due to pyogenic bacteria.

The illustrations in the book—and these are undoubtedly the principal feature of the publication—consist in large part of photomicrographs reproduced by the heliotype process, and here it is a pleasure to testify to the complete success of the photographs and their reproduction. We know of no similar aggregation of photomicrographs covering this ground, and rejoice that such a collection as those to be found in the book before us is now available to students. The subjects have been evidently very carefully chosen, and suitable powers of magnification have been employed. In a majority of instances the details are sharp. This is especially true if a hand-lens be used to examine the heliotype reproductions. The authors have been wise in making a majority of the photographs with low amplification. Photography does not yet yield such good results with high powers as it does with low. In a few instances the effects would have been much better had better specimens been available for the photograph. One can easily see that the fixation has been imperfect in some of the preparations. But pathology is not like normal microscopic anatomy. One can not multiply preparations at will, but must avail himself of those which come into his hands. The legends to the figures have been carefully written and are very helpful as explanations. The photographs are supplemented by a number of lithographic plates.

If the atlas had been published as a series of plates with legends, and the text omitted, there would have been but little to criticise. As it is, the errors in the text may easily be corrected in a subsequent edition, when, no doubt, also, the typographical errors met with will disappear. We notice, among others, "Erlich" for "Ehrlich;" iodine" for "iodide;" "Friedlander" for "Friedländer;" "Lowit" for "Löwit;" "Stohr" for "Stöhr;" "lumene" instead of "lumina;" "thrombus and embolen" instead of "thrombosis and embolism;" "Marschalkz" for "Marschalko."

The terminal section of the volume deals with the principles of optics and photomicrography. It will be welcomed by those who wish to do practical work in this interesting field. Full directions for setting up photomicrographic apparatus, for supplying the source of light and for the arrangement of filters, are given. Hints as to the kinds of photographic plates to employ, modes of developing the plate, and the method of making lantern slides are successively dealt with. There is a short note on tricolor photography—a method which has been employed to a very slight extent in the illustration of the volume before us. The results, as judged by plates XXXVA and XXXVB do not warrant any very extensive use of this method at present. While we have frankly pointed out the defects of this volume, we do not wish to leave too unfavorable an impression of it. Students who seek a guide for the laboratory work in a course in pathologic histology may be helped by the illustrations in this volume of Gaylord and Aschoff.

THE CENTURY BOOK FOR MOTHERS. A Practical Guide in the Rearing of Healthy Children. By Leroy Milton Yale, M.D., Formerly Lecturer on the Diseases of Children at Bellevue Hospital Medical College, New York; and Gustav Pollak, Editor of "Babyhood." Cloth. Pp. 461. Price, \$2.00 net. New York: The Century Co. 1901.

The scope of this work is advice to the prospective mother before her babe is born, and for the care of her child through

its infancy. The chapter on Preparation for Motherhood is brief but sensible and practical, including diet, dress, exercise, care of the breasts, selection of the nurse, outfit for the lying-in chamber, for the baby basket, etc. This is followed by chapters on the nursery, the baby's bath, hours of sleeping, feeding, air and exercise, dress, growth and development, disorders from improper feeding, evidences of illness and domestic treatment. The latter includes the simplest of remedies and remedial measures, how to give medicines, nursery emergencies, etc. The above is but a brief outline of what appears in part one. In part two are considered all the various ailments to which children are subject. The method adopted in this part is peculiar, certainly practical, although not systematic. It is in the form of replies to queries sent by mothers to the authors while they were editors of the magazine *Babyhood*. The queries cover all the perplexities of daily nursery life and include every simple ailment. The answers are full, sensible, and all that could be desired to satisfy the most querulous and anxious mother. The advice and directions given are just what might be expected from a conscientious scientific physician to one of his patients. The language used is free from dogmatism, simple in style, and void of technicalities. The object, as stated by the author, is to help the intelligent mother to become the alert and judicious guardian of the nursery rather than to tempt her to play the part of the physician and to dabble in dosing. The book is one that can be conscientiously recommended to a young mother by her physician. We know of none that is so thoroughly satisfactory in every way and we only wish there were more of such books to put into the hands of the laity.

### Miscellany.

**Pasteur Treatment of Hydrophobia in Mexico.**—The last *Boletin* of the Mexican National Board of Health reports that since the Pasteur treatment of hydrophobia was introduced in 1888, 4000 persons have been treated. The total mortality has been only 3 per 1000.

**Medal for Fournier.**—Professor Fournier of Paris relinquishes his clinic at the Hospital Saint Louis with the present scholastic year. His friends intend to present him with a medal; subscriptions are received by Dr. Rueff, 106 Boulevard Saint Germain, Paris. A subscription of 25 francs or \$5, entitles one to a copy of the medal.

**Mechanical Cure of Fetid Atrophying Rhinitis.**—In order to induce proliferation at the atrophying points, Flatau implanted a row of ivory pegs at the point of insertion of the lower turbinal in two cases of fetid, atrophying rhinitis. The results were evident in the course of a few months; the bone had increased in size and the secretions had altered their nature, with almost complete cure in two years. He states in his communication to *Deutsche Praxis*, 1900, 12, that the implanting of the pegs after spraying with hydrogen dioxide and submucous injection of cocaine, was a very simple operation.

**Wiring an Aortic Aneurysm.**—Dr. J. M. T. Finney operated on an aneurysm of the arch of the aorta by wiring and electricity at the Good Samaritan Hospital, December 8. The patient, a mulatto, aged 41, had a large pulsating globular mass projecting forward in the upper sternal region. A large aspirating needle lacquered to near its point was thrust first horizontally through the skin over the tumor, then turned perpendicularly and thrust directly down until blood began to flow through it. A wire coiled on a spool was then passed in through the needle until 10 feet had entered. Then a galvanic current of 9.5 milliamperes was passed through it, the negative pole being over the back, the positive connected with the end of the wire. The current was passed for one hour, the blood flow ceasing as soon as the connection was made. The patient felt no pain, being anesthetized with cocaine. Dr. F. says 44 cases have been operated on by this method, the recoveries being one in five. He has had 2 recoveries in 9 cases. The wire which he uses consists of 30 parts of copper and 1000

of silver. He prefers the mild current for an hour rather than a strong one for a few minutes. The patient is doing well up to the present (December 14). After using the current the needle was withdrawn, the wire cut off near the surface and its end pushed under the skin.

**Counter-Irritation in Southern Luzon.**—The following letter and photograph recently received by the Surgeon-General of the Army is published as an item of interest relating to primitive medical practice among the natives of the Department of Southern Luzon:

TABACO, ALBAY, P. I., Oct. 20, 1901.

*Chief Surgeon, Nueva Caceres:*—I have the honor to forward the enclosed photograph to illustrate the peculiar Bicol practice known as *Tangkong*. This skin stretching is quite universally practiced among the Bicolos and while it obtains more generally among the poorer classes I have occasionally seen a suspicious bump on the back of the neck of even high caste Filipinos. The elevations observed in the picture are the result of repeated stretchings of the skin and I have seen instances where the hypertrophy was so pronounced as to resemble the mammae of an ordinary girl at puberty. The operation is performed by grasping the skin of the back of the neck firmly between the semi-flexed index and middle fingers, draw-

ing it out as far as possible and letting go again and again. As the skin is successively stretched it becomes quite elastic and when it becomes very sensitive a strong salt solution is applied and the operation is repeated. It is used as a general cure-all, but its greatest virtue lies in the relief it affords in severe headache. One can readily understand that such would be the case, since it is nothing more or less than counter-irritation, but why a whole nation should employ such a method until the resulting hypertrophy of the connective tissue has made the tangkong almost as permanent a feature of these people as their dark skin or straight hair is hard to explain. The operation is usually practiced by the *Parabolong*, as the native medicine man is called, but not necessarily so, as any one can do it. Leeching, cupping, the application of cataplasms or vesicants and the employment of the scarificator are general procedures in most diseases and the sick Filipino is fortunate if he escapes having at least one of these practiced upon him, even while employing one of the more intelligent native physicians. I have seen native prisoners with hundreds of scars from scarification upon their bodies. The accompanying photograph was taken of a number of prisoners of war, selected at random from a company, every member of which showed some evidence of having submitted to the process. Surgeons in the Philippines must have noticed this matter and probably know more of it than I am able to tell, but I merely describe it in order to enrich the archives of the Department of Southern Luzon.

GEORGE A. ZELLER,  
Capt., Asst. Surg., U. S. V.

## Societies.

**Memphis (Tenn.) Medical Society.**—This Society met December 17, and elected the following officers: Dr. Alfred Moore, president; Dr. Edwin Williams, vice-president; Dr. James L. Barton, secretary and treasurer.

**Weber County (Utah) Medical Society.**—At the regular meeting of this Society the following officers were elected for 1902: Dr. Chester E. Coulter, president; Dr. Amasa S. Coudou, vice-president; Dr. George A. Dixon, treasurer; Dr. Harry B. Forbes, secretary, and Dr. James M. Harris, librarian.

**Pulaski County (Ill.) Medical Association.**—This Association met for organization at Mound City, and elected Dr. Marcus L. Winstead, Wetaug, president; Dr. John F. Hargan, Mound City, vice-president, and Dr. Charles J. Boswell, Beechwood, secretary and treasurer.

**Hamilton (Ontario) Medical Association.**—At the annual meeting of this body, held December 6, the following officers were re-elected: Dr. Robert R. Wallace, president; Dr. Edward B. O'Reilly, vice-president; Dr. Walter Langrill, treasurer; Dr. W. Crawford, corresponding secretary, and Dr. Warren White, recording secretary.

**Tri-State Medical Association of the Carolinas and Virginia.**—The fourth annual meeting of this Association will be called to order in Asheville, N. C., February 25. All fellows intending to read papers will please communicate with the secretary, Dr. Hubert A. Royster, Raleigh, N. C., giving title, not later than January 15.

**Orleans Parish (La.) Medical Society.**—At the annual meeting of this Society, December 14, the following officers were elected: Dr. Hermann B. Gessner, president; Dr. Albert Graner, Dr. Sidney P. Delaup, and Dr. Gordon King, vice-presidents; Dr. I. I. Lemann, recording secretary; Dr. Jacob A. Storck, librarian, and Dr. William H. Seemann, treasurer.

**New York Academy of Medicine.**—Dr. V. P. Gibney has been elected vice-president; Dr. Walter Lester Carr, a member of the Committee on Admissions, and Dr. Walter B. James a member of the Committee on Library. In the Section on Laryngology and Rhinology, Dr. Emil Mayer has been elected chairman, and Dr. Z. L. Leonard, secretary of this Section.

**Allen County (Ind.) Medical Society.**—The annual meeting of this Society was held at Fort Wayne, Ind., December 23. Dr. W. A. Evans, Chicago, delivered an address on the "Economic Relations of Tuberculosis." The following officers were elected: Dr. Samuel H. Havice, president; Dr. Elmer E. Morgan, secretary; Dr. William P. Whery, treasurer, and Drs. George L. Greenawalt, George B. M. Bower and Budd Van Sweringen, censors, all of Fort Wayne.

**Alexander County (Ill.) Medical Association.**—The physicians of Alexander County met at Cairo, December 17, and organized this Society with the following officers: Dr. Samuel B. Cary, president; Dr. James W. Dunn, vice-president; Dr. John T. Walsh, secretary and treasurer, and Drs. Alpheus A. Bonduant, James H. Oakley and James McManus, censors, all of Cairo. The first regular meeting will be held in January, and the annual meeting in April.

**Oklahoma County (Okla.) Medical Association.**—This Association was organized December 4. At its second meeting, December 11, by-laws and constitution were adopted and a paper on "Penetrating Wounds" by Dr. R. D. Long, Oklahoma City, was read. The society will meet semi-monthly in Carnegie Library, Oklahoma City. Its officers are: Dr. Claudius B. Bradford, president; Dr. R. D. Long, vice-president, and A. D. Young, secretary and treasurer.

**Tri-State Medical Association.**—The Tri-State Medical Association of Western Maryland, West Virginia and Western Pennsylvania, met in semi-annual session at Cumberland, Md., December 19. Papers were read as follows: "The Radical Cure of Hernia," Dr. R. W. Stewart, Pittsburg; "The Medical Side of Surgical Cases," Dr. I. N. Love, New York; "Incipient Tuberculosis," Dr. C. C. Johnston, Pittsburg; "Uremia," Dr. C. C. Jacobs, Frosburg; "Pneumonia," Dr. A. F. Speicher, Elk Lick, Pa. A banquet followed.

**New York State Charities Aid Association.**—At the annual meeting of this Association held in New York during the past week, Dr. George G. Wheelock reported that the charities administration of the Borough of Manhattan had been improved by providing two salaried resident physicians for the insane pavilion at Bellevue Hospital. There was still need

for the exclusion of pauper labor in the department, and a new building for Bellevue Hospital was urgently demanded. Reports from the county committees throughout the state showed a general improvement in the almshouses, but every state hospital is now caring for from 100 to 500 more inmates than can be properly accommodated.

## THE WESTERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

*Eleventh Annual Meeting, held in Chicago, Dec. 18 and 19, 1901.*

President, Dr. A. F. Jonas, Omaha, Neb., in the Chair.

An Address of Welcome was delivered by Dr. Alexander Hugh Ferguson, Chicago, to which an eloquent response was made by Dr. Joseph Eastman, Indianapolis.

### An Old Shoulder Dislocation, with Report of a Case.

DR. J. RUDIS-JICINSKY, Cedar Rapids, Iowa, read a paper with this title. The object of the author in making this report of an apparently simple case was to show what the x-ray could do for the profession in the investigation of luxations, fractures, and in observations of the growth of the callus, the bones themselves, etc., and to furnish an aid in the interpretation of the x-ray findings. Before one could interpret correctly the fluoroscopic image or the skiagraph of certain parts, when their relationships were altered by disease or trauma, he should have always before him a skiagraph picture of the normal parts, and of their normal relations. After taking all the other precautions of a proper technique into consideration, one could not go astray. Moreover, the eye would be prepared to take in much which would otherwise not be seen. The x-ray enabled one to determine through a plaster cast or other dressing the exact position of the fragments. After reporting a case at great length of an old shoulder luxation, the author dwelt upon the value of the x-ray in cases of fractures, etc.

DR. LEWIS SCHOOER, Des Moines, Iowa, endorsed the value of the x-ray in old dislocations of the shoulder, especially in cases where the swelling was so great as to obscure some of the landmarks and render the diagnosis difficult by the usual method. While in nearly all cases the examining surgeon could make a diagnosis with satisfaction without the aid of the x-ray, yet it was a consolation to have one's diagnosis verified by a competent operator of the x-ray machine.

### Treatment of Irreducible Backward Dislocation of the Astragalus by Opening the Joint and Repositing the Same.

DR. W. JEPSON, Sioux City, Iowa, after detailing a case and going extensively into the literature of the subject, summarized his observations as follows: 1. His own experience and the results of recorded cases led him to believe that it would rarely be possible with present knowledge and technique to bring about a reduction of a backward dislocation of the astragalus without opening the joint and bringing about a reposition of the bone by direct manipulation. 2. With our present command of aseptic surgery he could see no reason why this should not be undertaken in all cases uncomplicated by severe infection, with good prospects of securing nearly a perfect result. 3. Removal of the astragalus should be reserved for such cases as where the bone was completely separated from its ligamentous attachments, consequently having no adequate source of blood supply. 4. If amputation be resorted to only when the dislocation was compound and infected to a degree impossible of removal, the patient's life was jeopardized by the septic intoxication or infection.

### Some Internal Injuries of the Knee Joint.

DR. M. L. HARRIS, Chicago, called attention to two varieties of injuries to the inner structures of this joint which, he believed, were more common than the attention heretofore given them would seem to indicate. These injuries might be produced in one of two ways: 1. By the direct application of force, as might occur in a fall upon the knee, or by the forcible impingement of a more or less pointed object against this

portion of the joint. 2. By pinching or crushing the apex of the mass in the angle between the femur and tibia, as might occur when these bones were slightly separated during hyperflexion or sudden wrenching. The cases narrated by the author illustrated the serious and persistent disablement that might occasionally result from comparatively slight pathologic changes affecting the inner structures of the knee joint, and showed the necessity of operative treatment in those cases following an injury in which the characteristic symptoms persisted after the usual treatment of the joint by rest and immobilization.

#### Ankylosis of Joints.

DR. JOHN B. MURPHY, Chicago, recommended arthroplasty for the relief of ankylosis without destructive bone defects. Ankylosis and contractures were of three varieties: 1, atrophy of soft parts; 2, union (fibrous and bony) between joint surfaces; 3, a combination of one and two. The essayist referred to the experimental work of Chlumsky, of Würzburg, who decided that the best way to relieve such joints was to treat them precisely on the same basis as one would non-union of fractures from the interposition of foreign material between the fragments. He experimented with several kinds of material, absorbable and non-absorbable, to determine the best material to use, but finally abandoned the use of foreign materials and resorted to a plastic operation in the neighborhood of the joint for its relief. The method of Chlumsky was described, the essayist stating that he had adopted it in several cases with good results.

#### Treatment of Dislocation of the Clavicle Through Open Wound.

DR. JAMES E. MOORE, Minneapolis, said that some recent writers had advocated the treatment of such a dislocation by wire suture, but he had been unable to find any literature upon the subject. Quite recently he had treated a case by cutting down upon the dislocated bone, replacing it and the surrounding soft parts, and fastening them there by means of silver wire and catgut sutures. The result was very satisfactory and the findings were instructive.

#### Etiologic Factors in the Production of Tumors.

DR. GEORGE HALLEY, Kansas City, Mo., read this paper. No theory had been broad enough to account for all the phenomena characteristic of benign or malignant tumors. Inflammatory conditions that almost invariably produced some kind of tumefaction were for a long time regarded as the principal factor in their production. Many things, however, in the inflammatory conditions in no way comported with the ordinary processes found in tumor growths, and the products of most of the tumor growths were utterly unlike those of the inflammatory process. But as inflammation was believed to be principally due to irritation, it was held to be the prime factor in the production of morbid growths. The author dwelt at length upon the various forms of tumors. One constantly occurring element in all benign tumors was the connective tissue. Sometimes it predominated and sometimes it was held in abeyance. Its presence was never wanting. Of all the tissues in the body, it most readily responded in physiologic activity to irritating processes. In inflammatory changes it was found to be the reconstructing agent. It was not wonderful, therefore, that we had in this tissue the essential part, if not the entire mass, composed of this tissue. Was the connective-tissue germ cell altered in quality? Had it been inoculated by a plastic material altered in quality by an irritant, or had there been a coalescence of protoplasmic germs from other tissues? We had not yet determined this, but he took it that along these lines, if not exactly, yet relatively near to it, would be found the true etiology of the benign tumor.

#### Surgical Procedures in Removal of Fibromyoma of Uterus.

DR. JOSEPH EASTMAN, Indianapolis, opened the Symposium on Fibromyoma by reading a paper on the above subject. He said the morphology of the tumor and the environment of the patient should be considered before selecting the method to remove the tumor. Clay, of Manchester, operated for the first

time, in 1844, for the removal of fibromyoma of the uterus. After speaking of the early history of removal of myoma of the uterus, Dr. Eastman described the first case that he operated on, Feb. 3, 1887; also the method pursued by him at that time, which can be found in the literature on this subject.

#### Myomectomy; Its Place in the Treatment of Fibromyoma of the Uterus.

DR. O. BEVERLY CAMPBELL, Chicago, said the operation of myomectomy was not applicable to all cases of fibromyomata of the uterus, but could apply only to well selected cases. This operation did not supplant panhysterectomy, hysteromyomectomy, and the different procedures for relief of fibromyomata, but took its place as one of the recognized rational procedures, and as it was a conservative measure, it should be the favorite procedure when possible. A critical bimanual examination through the vagina and rectum under complete anesthesia would usually admit of the diagnosis of cases amenable to this operation. All of the different varieties of fibromyomata, namely, the subperitoneal, the interstitial and the submucous, may be treated by this method. By many operators it had been limited to the pedunculated subperitoneal variety. However, it had now been successfully applied to every variety of fibromyomata, with satisfactory results as to the immediate mortality rate and permanency of cure. The author concludes that myomectomy should be the preferred method in every case where possible to do so without extra risk to the patient, and where the ovaries can be conserved with the uterus. Operative interference should be advised in every case of fibromyomata where after a careful examination myomectomy was considered possible. The operation of myomectomy was, at all times, as safe in cases where it was applicable, as hysteromyomectomy and panhysterectomy, and very many times almost a minor procedure practically free of risk. That the early diagnosis of fibromyomata should be insisted upon with a view of enlarging the percentage of cases in which myomectomy may be applicable.

#### Management of Uterine Fibromyomata Complicated by Pregnancy.

DR. MILES F. PORTER, Fort Wayne, Ind., after referring to the literature on this subject and reporting an interesting case, gave the following conclusions: 1. Pregnancy was a frequent and serious complication of uterine fibromyomata. 2. If, because of their size or location, they were likely to interfere with gestation or jeopardize the patient's life, they should be removed. 3. Each case was a law unto itself, and should be treated accordingly. 4. The tumor and not the pregnancy was the disease, and therefore any procedure which resulted in leaving the tumor and removing the pregnancy was unjustifiable. This, of course, was not meant to apply to those cases in which the fibroids did not interfere in any way, either with gestation or labor. 5. Pregnancy did not materially add to the risk of operations for uterine fibroids, so far as the mother was concerned. 6. The life of the mother, the life of the child, and the question of future offspring were the most important matters to be considered in reaching a conclusion as to the treatment of a case of uterine fibroids complicated with pregnancy.

#### Treatment of Fibroids of the Uterus by Electricity, and Present Status.

DR. FRANKLIN H. MARTIN, Chicago, said that in the light of our knowledge there was a time when the galvanic treatment of fibroids of the uterus by experts was legitimately the most conservative treatment possessed for a majority of those troublesome neoplasms. Now, the removal of fibroids with the knife by experts was the most conservative treatment for the majority of these difficulties. There was a time when the author submitted practically all his fibroid cases to the Apostoli treatment, because this treatment scarcely ever failed to materially benefit the patients; it symptomatically cured a large percentage, and occasionally the tumor seemed to disappear. It accomplished these results without subjecting the patient to a procedure which possessed any legitimate mortality. Gradually the evolution of the surgery for fibroids had reversed the relative position of the galvanic treatment. He

considered vaginal and abdominal hysterectomies and myomectomies for fibroids, giving rise to serious symptoms, with their legitimate mortality reduced to one and two per cent., as remedies more conservative in their results than the treatment of the same tumors with electricity. He believed this, because hysterectomies and myomectomies, with a small percentage of risk, were the only remedies which absolutely relieved the difficulties in all cases. Electricity relieved frequently, symptomatically cured, but seldom actually removed the tumor, and the treatment was tedious to the patient, and occupied much time of the physician in administering it. The present status of the electrical treatment of fibroids of the uterus was, in his opinion, that it had been properly superseded by surgery as a conservative remedy. He now recommended the former in the following cases only: 1. As a local and general tonic, and as a relief of pressure and reflex pains and of hemorrhage in cases with complications contra-indicating surgery. 2. In all interstitial fibroids where operative assistance was absolutely refused by the patient. 3. In tumors of small size of the interstitial variety in which hemorrhages were the principal symptom in women within one or two years of the menopause.

DR. W. O. HENRY, Omaha, Neb., in the discussion which followed the Symposium, thought that the electrical treatment of these tumors was overdone, and that to-day it was largely abandoned. As to myomectomy where there was no complications requiring the removal of the tubes and ovaries, where the growth did not involve the entire depth or thickness of the uterus, so that this organ might be left intact, it was the operation to be performed. He agreed with Dr. Porter as to the removal of fibroid tumors that complicated pregnancy. As to panhysterectomy for uterine fibroids, he objected to it, as a rule. He thought it was better to save as much of the cervix as possible, thus securing a better vault for the vagina and a better support for the uterus.

DR. VAN BUREN KNOTT, of Sioux City, Iowa, said that myomectomy as a conservative procedure in the treatment of neoplasms of the uterus needed no support. It was commonly accepted to-day as the method of election in cases in which it was applicable. He recalled a case of myomectomy performed on a woman three months advanced in pregnancy, who was subsequently delivered at full term of a healthy male child.

DR. B. B. DAVIS, Omaha, said, as to myoma complicating pregnancy, that the tumor should be removed, if possible, before the woman became pregnant, but frequently patients consulted physicians with that complication. He endorsed practically all Dr. Porter had said in regard to the subject. He condemned the induction of abortion before delivering or removing the tumor, and mentioned a case in which he was called in consultation, one of the physicians recommending that that would be the best method.

DR. C. H. MAYO, Rochester, Minn., mentioned the case of a woman, 30 years of age, on whom he operated last June for a tumor complicating her first pregnancy. The tumor proved to be a degenerating fibroid, with free fluid in the abdomen. The adhesions and tumor were much larger than the pregnant uterus. The tumor was removed; the woman made an uninterrupted recovery, and he expected later to be compelled to do a Porro operation, but in due time the woman was delivered of a healthy living child and recovered.

DR. A. C. BERNAYS, St. Louis, Mo., expressed himself in favor of myomectomy where it could be done. He recalled two cases of very large fibroids in which he found that myomectomy was an excellent method of enabling him easily to make a hysterectomy. He believed that in both of those cases he could not have made a hysterectomy without making a myomectomy of the very large tumor first.

DR. CHARLES H. WALLACE, St. Joseph, Mo., was interested in the paper of Dr. Campbell, and said that myomectomies were of recent origin. Myomectomy was comparatively easy of performance in properly selected cases. As to tumors complicating pregnancy, he would follow the advice of Dr. Porter.

DR. J. N. WARREN, Sioux City, Iowa, combated the idea that myomectomy was an easy operation to do, and without

any particular danger attending it. He regarded it as a formidable operation, and always attended with considerable hemorrhage, excepting in the subserous variety, where there was a pedicle and the surgeon could incise the serosa around it and simply peel the tumor out; but in the majority of cases where he had a combination of the interstitial and subserous varieties, it might be necessary to go through the entire thickness of the uterine wall; then it was not a simple operation. It was one that required not only great dexterity, but good judgment in determining exactly the limits of the myomatous mass which was to be removed.

DR. W. A. TICHENOR, Chicago, seconded the remarks of the last speaker as to the formidability of myomectomy. If there were one or two small tumors close to the peritoneal surface, it was not difficult to shell them out. On the other hand, if there were eight or nine tumors of fair size, and the surgeon undertook to remove them all from the surface of the uterus, he would get the uterus pretty well riddled with incisions for their removal, and it was not a safer operation, in his judgment, than a hysterectomy.

DR. JAMES E. MOORE, Minneapolis, endorsed the paper of Dr. Campbell. All would agree that what was conservatism a few years ago was no longer conservatism. There was one point he wished Dr. Campbell had emphasized, namely, the possibility of doing myomectomy through the vagina. Within three weeks he operated through Douglas' pouch for the removal of a tubal pregnancy before rupture, and incidentally removed two fibroids, one of which was situated in the anterior wall of the uterus, well down toward the bladder, yet it was not difficult to remove it.

DR. DONALD MACRAE, JR., Council Bluffs, Iowa, commended the paper of Dr. Campbell, and said it was the sinew of conservatism. These fibroid tumors should be operated upon and removed as soon as they are diagnostic.

DR. LEWIS SCHOLLER, Des Moines, Iowa, said the trend of the discussion seemed to be in the direction of operating on uterine fibroids by some method or other. He thought there was hardly a practitioner in the room who did not know of some of these fibroids having existed for ten or fifteen years in women without producing any disturbance. He did not think it was well to operate for their removal as soon as they were discovered. There were some women who had passed the menopause, others who were near it, and still others who would probably not give birth to children, in whom these fibroids caused absolutely no trouble. Some of these cases could be left alone.

The discussion was then closed by the various essayists.

*(To be continued.)*

#### FIFTH DISTRICT BRANCH OF THE NEW YORK STATE MEDICAL ASSOCIATION.

*Special Meeting, held at Newburg, Nov. 20, 1901.*

President, Dr. Emil Mayer, in the Chair.

#### Appendicitis.

DR. JOHN B. DEEVER, Philadelphia, read a paper on this subject. He said that he had operated for this disease several hundred times a year, yet he felt that the only truly conservative course in the treatment of this affection was the resort to the aseptic scalpel of the surgeon as soon as the diagnosis of appendicitis had been made. The first step to a correct understanding of this affection was a study of the autemortem and not the postmortem pathology. If the profession generally had an opportunity to see a large number of cases of appendicitis on the operating table the lesson there learned would not be lost. The three cardinal symptoms are pain, tenderness and rigidity. There is usually a sudden onset of pain in a healthy individual. The typical tenderness of appendicitis was not that carelessly elicited, but that obtained by the pressure of a single finger, and it was confined to a very small area. Rigidity of the neighboring part of the rectum was usually present from the onset, though it could not be detected frequently at first because of the delicacy of palpation required. A light touch was essential and the palpation

should be begun at some distance from the affected region. The diseases most apt to be confounded with appendicitis are typhoid fever, extra-uterine pregnancy, cholecystitis and acute mechanical intestinal obstruction. Strangely enough typhoid fever was the most difficult to differentiate from a mild case of catarrhal appendicitis. Gurgling was not usually present in appendicitis and the presence of a leucocytosis would usually exclude typhoid fever. The history, the location of the point of greatest tenderness and the character and distribution of that tenderness together with a rectal examination, would usually enable the physician to differentiate between appendicitis and cholecystitis. Appendicitis is not infrequently accompanied by more or less jaundice. The practice of keeping a patient under observation to see if the case would become operative was to be severely condemned. He did not hesitate to say that it was unjustifiable to delay after the diagnosis of appendicitis had been made. Time and again had he seen valuable lives sacrificed on this altar of procrastination. The ideal time to operate in appendicitis was in the stage of appendiceal colic. The procrastination which allows a walled-off abscess to form was to be deprecated. In the healing of an appendiceal abscess the contraction attendant upon the process of healing often results in acute mechanical obstruction. So much did he fear this complication that he was accustomed to operate as soon as there were present paroxysmal abdominal pain, nausea, vomiting, slight tympany and an inability to pass flatus or to have a movement of the bowel as a result of the use of purgatives or high enemata. It was most important to evacuate all abscesses, using no chemical antiseptics for irrigation.

DR. PARKER SYMS, New York City, said that some years ago a man was thought to be too radical who advised operation in all cases of appendicitis, but the prevalent opinion of the present day was in favor of such a course. In a case of fulminating appendicitis before perforation had taken place there were no symptoms except such as would be found in cases of very mild catarrhal appendicitis. An operation done before the occurrence of perforation was one of the simplest in surgery.

DR. L. W. HOTCHKISS, New York City, said that the position of a surgical practitioner who has no well-formulated views on the treatment of appendicitis is a most unfortunate one, and it is not surprising that such a person shrinks from seeing these cases in consultation. In the opinion of the speaker, there was no more danger from operating during an attack of appendicitis than in the interval, and he thought the position taken recently by many in favor of the interval operation had done a good deal of harm. He was personally in favor of an early and radical operation, and the employment of a simple technique, doing away as far as possible with the use of gauze.

DR. IRVING S. HAYNES, New York City, said that it was not always possible to find the appendix when it is only moderately tender. The appendix often occupies a position across the psoas muscle, and hence if the patient were instructed to raise the knee, thus making this muscle tense and bringing it up nearer the surface, it would be found easier to elicit this tenderness.

DR. E. D. FERGUSON, Troy, said that he was one of those who regard appendicitis as a surgical disease, yet he could not altogether agree with the statements made in the paper. It should not be forgotten that the operation done in the height of the attack furnishes a mortality of from 15 to 17 per cent., according to statistics recently published by Dr. Deaver himself. What was the natural mortality of all cases of appendicitis when not operated on? He had long pondered upon this question, and had in the past few years evolved a rule for his own guidance. He was willing to admit that the interval operation had been overworked, yet according to Dr. Deaver's statistics the mortality of the interval operation is less than one per cent. He knew of no more reliable and extensive statistics than those from which he had just quoted, and hence these figures brought us face to face with an important practical question. According to his own experience, purulent

accumulations occur in 10 per cent. of cases of appendicitis, and the explosive forms in less than 2 per cent. If one operated within 24 hours it was probable that there would not be much septic material outside of the appendix, and one could do an aseptic operation with excellent chances of success. We should be just as thorough as Dr. Deaver in removing pus pockets, but it was an entirely different matter to remove an appendix. It was often most difficult to find the appendix even on the postmortem table, and hence to go on and separate adhesions in the living subject seemed to him highly improper. The appendix should be removed if it could be done without danger of exposing the uncontaminated portion of the peritoneal cavity.

DR. DEAVER replied that the mortality of 15 per cent., quoted by the last speaker, had been correctly given, but this rate had been produced very largely by operating on many cases coming first to him with large abscesses. One could not rightly compare cases in which the diagnosis had been made positive at operation with those in which it was only conjecture, there having been no confirmation of the diagnosis by actual inspection. He was most careful not to disseminate sepsis, and for that reason he opened into the healthy peritoneum beyond the abscess, and by the proper disposition of gauze was able in most cases to secure good results. The whole matter resolved itself into a question of technique.

#### Etiology and Treatment of Bright's Disease.

DR. CHARLES E. QUIMBY, New York City, read this paper. He divided the cases of Bright's disease into two great classes, those of pure inflammation and those of cellular degeneration. The chief etiologic factors were: 1, defective vascular supply; 2, toxic depression of cellular metabolism, and 3, functional strain. He thought there was more renal disease due to obstipation and impaction of feces than to any other one cause. The first sign or symptom of Bright's disease would be found in the vascular system. Successful treatment was possible only in the early stages. The perverted function of the nutrient organs must be restored, the toxins neutralized and the kidneys let alone. One should refrain from increasing the toxic strain by giving digitalis. When pneumatic differentiation could be had other methods of stimulating the heart would not be required. The main purpose of the paper was to show that chronic Bright's disease is the result of very common conditions, and that success in its treatment depends upon skill in detecting the signs of approaching trouble and functional failure and averting the same.

DR. JOHN WINTERS BRANNAN, New York City, said that the chief points in the treatment of Bright's disease were the restriction of proteid food, the prohibition of strong alcoholic liquors, the encouragement of a free use of the alkaline waters and the promotion of the action of the skin and bowel. The patient should be warmly clad and chilling of the body surface should be avoided. Occasionally drugs were of service. Nitroglycerin was sometimes of great value. Laxatives must be given to secure a free action of the bowels. In the main, the treatment of Bright's disease was hygienic and dietetic rather than medicinal. Scarlet fever was the most important cause of renal disease. Two cases were narrated, one the result of scarlet fever, and the other dependent upon chilling of the surface of the body.

DR. F. P. HAMMOND, New York City, spoke of the difference in red and white meats in their relation to the production of toxemia. It had been stated that persons may take white meat because of the shortness of the fiber without such disturbance of digestion that would result from the ingestion of red meat, a point worth remembering in connection with the management of cases of Bright's disease, where so much depends upon the avoidance of toxemia.

DR. QUIMBY, in closing, referred to the question of dietetics. His rule was to exclude meats of every kind, and he was sure that the results were far more satisfactory than where half-way measures were used. He would also exclude eggs. Sometimes a diet of hot water and meat would succeed when an exclusively vegetable diet would not answer well. A mixed diet seemed to be particularly harmful.

DR. E. ELJOT HARRIS, New York City, introduced the following resolution, which was adopted:

*Resolved*, That the Committee on Public Health of this District be requested to investigate the matter of the water supply and the ice supply of the cities and towns of this district, and report back a plan for the better protection of the public health from the contamination of drinking water.

DR. FREDERIC W. LOUGHRAN, New York City, chairman of the Committee on Public Health of the Fifth District, called attention to the unusual prevalence of smallpox at this time throughout the state, and the need for legislation to secure systematic vaccination. He said that statistics show that smallpox has gained a foothold only in those countries having no compulsory vaccination law. The members were urged to make personal effort to secure the needful legislation.

#### CINCINNATI ACADEMY OF MEDICINE.

*Regular Meeting, held Nov. 25, 1901.*

The President, Dr. N. P. Dandridge, in the Chair.

##### **Mycosis of the Fauces.**

DR. J. A. THOMPSON reported the case of Miss B., aged 18 years, working in a tobacco factory. In December, 1900, her throat felt uncomfortable and she examined it herself with the aid of a hand mirror. Seeing a number of white spots on the tonsil she became alarmed and consulted a physician. She was under the care of this practitioner for several months. During this there were attacks of inflammation, when the throat would be moderately painful. There were other intervals when there would be no subjective symptoms. At no time was there any fever or any other constitutional symptoms that might be traced to the local disease in the throat. The white spots were always present on examination. Examination showed a grayish-white mass protruding from every crypt on the left tonsil. Some of these grayish-white papillae were black at the summit. There was no congestion of the membrane. The lower portion of the right tonsil was unaffected. At the upper portion between the pillars of the fauces, where they were protected from mechanical irritation, were three large outgrowths. The patient had never complained of any discomfort about the tongue, but examination with the laryngoscope showed three affected nodules in the lingual tonsil. The above symptoms are sufficient to make a diagnosis of that rare condition—mycosis of the fauces. This disease is due to a growth of some kind of mold. Molds are frequently present in the mouth, but only in rare instances do they find conditions favorable for their growth. The changes which make it possible for them to develop in the fauces are not known. In the few reported cases an attack of acute inflammation like follicular tonsillitis or diphtheria seems to have preceded the growth of the leptothrinx. The growth may be either superficial or deep-seated. It may grow either on the epithelium or penetrate and destroy it. It generally grows in the crypts of the tonsils and protrudes from their mouths. From the tonsil the growth usually extends to the lymphatic tissue at the base of the tongue, the lingual tonsil, and may involve other parts of the faucial mucosa. There is little or no inflammation of the affected mucous membrane. The subjective symptoms are stiffness and soreness of the affected parts. The masses in the crypts of the tonsils can be differentiated from the cheesy contents frequently found there by the difference in color and by the fact that the cheesy mass can be easily pressed out while the mold can not be separated without rupture of blood vessels and some hemorrhage. The only disease which it resembles in appearance is acute follicular tonsillitis. The inflammatory and constitutional symptoms of the latter disease together with the history should make the differentiation easy. Mycosis of the fauces is not dangerous to life, but there is no tendency to spontaneous recovery. Without treatment the disease usually persists as long as the patient lives. Local applications of medicines to the affected areas seem to have no influence on the growth of the mold. The only successful treatment has been the destruction of the membrane from which it grew, either by the galvano-cautery

or by direct excision. In the present case the treatment adopted was excision of the infected areas in the tonsil with the Myles tonsil punch. Examination of the removed portions showed that the growth had extended deeply into the tissues of the tonsil. The galvano-cautery was used on the infected areas in the tongue. While the process of cure was tedious, the final recovery was complete.

##### **Apoplexy in the Visual Center Without Any Other Symptom of Motor or Sensory Paralysis.**

DR. LOUIS STRICKER reported the case of a laborer, 60 years of age. He related that during the previous two weeks he had been employed in the preparation of mushroom beds in a closed cellar. In doing this he had hauled and spread over the floors some twelve loads of manure, and at night, on coming out of this cellar, he always felt more or less dizzy, his eyes were suffused with tears, but that gradually this latter condition gave way to excessive dryness. On the afternoon of September 27, he states, on coming up out of the cellar he seemed even more dizzy than usual, and his gait was so unsteady that a policeman meeting him inquired if he were drunk. The officer assisted him home where he immediately collapsed into a chair, and during the course of the evening gradually sank into what appeared a deep sleep. The people with whom he was making his home tried to get him upstairs, but only succeeded in getting him as far as the back staircase where he finally woke at about 4 a. m. He groped his way as best he could to his room and after a day's intermission, resumed his work; but from this day forward he found that his vision was very much blurred and that he could not read. He gives a family history of being a widower, 60 years of age, having raised a family of seven children; that he drinks moderately, does not smoke, denies all venereal disease, and states that he has never had any serious illness. Examination of his heart shows this to be normal, but evidences of atheroma are evident and his pulse is not compressible. This case presents two important and essentially different conditions. First, that relating to the conjunctivae, and second, that connected with his sight. On inspection, lower lids were relaxed, and the conjunctivae dry and glistening. He stated that this condition had only made itself evident since he had been occupied in the cellar spreading this manure. This fact is interesting in that it shows a form of conjunctivitis particularly apt to occur in stablemen. The gases which arise from the manure are ammoniacal in nature, owing to the urea present in the horse urine. This ammonia gas leads to conjunctivitis, excoriations and blepharitis, so frequently observed in stablemen. The ammonia gas inhaled in a closed cellar may have been sufficient to have stimulated the heart's action to a degree capable of producing a cerebral hemorrhage, in a case such as the present, where there are atheromatous changes in the vessels, and thus lead to a small localized hemorrhage. The second condition was a localized hemorrhage. The man stated that everything viewed appeared to be partially enveloped in a cloud, that at a distance he could read fairly well, but that it was impossible for him to read a paper, since the upper half of all the letters were practically gone. If he looked at an object in the ordinary way, he could not see it, but if he turned his head toward his left and then looked at objects, they appeared perfectly clear. In looking at an object he stated that three-fourths of it was clear, whereas the upper right quadrant was wanting. The same condition was disclosed where each eye was examined separately for this symptom. Hence attention was immediately attracted toward some form of hemianopsia. His fields were taken, as per charts, disclosing a sector-like defect in the right left eye from 15 degrees to the nasal side to 105 degrees to the temporal; in the right eye, from 15 degrees to the temporal side to 105 degrees to the nasal. Both fields were slightly contracted, and in the area of the defect there was still an area of about five degrees extending around the point of fixation. His color sense was perfect in the retained portions of his fields. Since then his fields have been regularly taken each week, and though the general size of the defective area has remained practically the same, still there has been this im-

portant improvement, in that the area around the center of fixation has gradually been increased in the left eye up to ten degrees, whereas, on the right, it is still about five degrees, the point of practical importance being that with the return of central vision he is again enabled to read and is no longer so conscious of this defect in his visual field. The defect being projected forward and to the left, would naturally suggest the lesion in the brain to be located in the right hemisphere. A careful examination disclosed that the consensual reaction of his pupils is perfect; that he has no paralysis of the sphincters of the pupil, or of accommodation, nor has he any paralysis of other ocular muscles. He showed no form of other sensory or motor paralysis nor did he disclose any other form of psychic involvement. The interesting question naturally was to try if possible to form some idea as to the location of the lesion. From its gradual onset it appeared to be a thrombus, or a small localized hemorrhage.

DR. R. B. TATE reported a "Case of Smallpox Simulating a Threatened Abortion."

DR. M. L. HEIDINGSFELD presented a patient with lupus erythematosus of the face in a girl of 10, treated with resorcin held in a solution of gelanthum, which remedy is capable of holding resorcin in 50 per cent. solution. The girl had only been under this treatment for a few weeks but in that time had shown a remarkable improvement.

#### Papilloma of the Bladder.

DR. JOSEPH RANSOFF presented a specimen of papilloma of the bladder removed two weeks ago from a man aged 40; for a year he had had frequently recurring hemorrhages from the bladder until he had become almost exsanguinated. He complained of great pain on urination; on account of blood clots in the bladder the cystoscope could not be used, but with sound in the bladder and finger in the rectum the tumor could readily be felt. Spinal anesthesia was used and a suprapubic cystotomy made; the tumor was found attached to the mouth of the left ureter from which it was removed by means of the thermo-cautery. The wound was not entirely closed as he feared vesical sepsis.

DR. H. H. HOPPE presented a case of recurrent epileptic seizures. A tumor was found at the superior portion of the left temporo-sphenoidal lobe, and should have produced sensory aphasia but did not. The tumor was the size of a hen egg and pressed against cortex. There had been no headache.

#### SAN FRANCISCO COUNTY MEDICAL SOCIETY.

*Regular Monthly Meeting, held Dec. 10, 1901.*

Dr. John C. Spencer in the Chair.

#### Gastrectomy.

DR. E. G. FRISBIE presented a case: A. G. B., male, aged 42 years; occupation, glass-blower. Previous history was good. Present trouble began in June, 1901, when he began to suffer pain after eating and "bloated feeling." Weight was 112. He presented himself October 14, weighing 105. Examination of abdomen revealed nodule about two inches long in left hypochondrium, rolled under finger and retreated under rib. October 15, examination of stomach contents after test meal gave the following result: No free hydrochloric acid present, lactic and butyric acids present. Diagnosis was malignant tumor of the stomach. October 24, operation was made by Dr. E. E. Kelly and Dr. C. A. Dozier assisting; incision was to left of median line over the tumor, which was found to occupy the lesser curvature of the stomach, extending from near the pylorus half way to the esophageal opening. Tumor was excised with a margin of one and a half inches of sound tissue at either side, more than half of the viscus on the lesser curvature and about half of the greater curvature being removed. Opening closed with three rows of sutures and the duodenum attached by a Murphy button to the lower angle of the stomach. Patient suffered almost no pain after the first six hours, vomited a little bloody fluid for two days, after which remained perfectly comfortable. Nutritive enemata were given till sixth day after operation, then liquid food by

stomach alone; some feeding by stomach began the fourth day. Murphy button passed on the fourteenth day, some soft food having been allowed three days before. Patient sat up on fifteenth day and went home on the twenty-first. One month after operation patient was able to eat salmon, bread, potatoes, rice, apple-sauce and milk to the amount of 27 ounces at one meal, digested perfectly and with no discomfort. Patient has gained 12 pounds in weight in six weeks since operation and is now engaged in his occupation of glass-blower, wearing an abdominal belt of pure rubber which seems to give better support than the ordinary webbing. Examination of the tumor revealed an adeno-carcinoma with much colloid degeneration.

#### The Uniform Principle in Performing Operations for Lacerated Perineum, Cystocele, Rectocele and Prolapse.

DR. HENRY J. KREUTZMANN read this paper. The object of plastic operative interference is to restore the parts to their normal condition, by bringing those layers of tissue into apposition again that were in apposition before their separation. In the so-called "classical" operations we find that they consist in the denudation of the vaginal tissue over the injured part and union of the wound surface through suture. In his opinion every one of these operations thus performed was lacking in the certainty of bringing the proper tissues into apposition in every case. The rational operation that will bring success consists in separation by careful dissection and direct, exact union of those layers of tissue which belong to each other. The practical application of this principle in the operations under discussion could be divided into four different acts: 1. Dividing the vagina, cutting down into the septum between vagina and bladder or between vagina and rectum. 2. The detachment of the prolapsed diverticle of the bladder from the vagina, if necessary from the uterus, or separation of the rectum from the vagina. 3. The careful apposition of the fascial tissue and of the muscles that belong to each other, by direct, exact, buried suture. 4. To finish the operation, the vaginal flaps may be resected and united or they may be united without any resection, as the individual operator sees fit in every single case. The way in which division of vagina and septum was made was immaterial. He made a short incision in the case of cystocele over its lower part, longitudinal or T-shaped, and divided from there bluntly to the sides and upward, separating the vagina from the bladder; then the median incision was carried forward as far as the case demanded, forming thus two flaps. In operations upon the posterior vaginal wall he made a crescentic incision from caruncle to caruncle on the margin between the vaginal mucous membrane and the outside skin, and separated bluntly the vagina from the rectum. The division in every case was carried as far as it was necessary for the exposure of the septum-fascia and muscles. To unite the septum-fascia it was necessary to carefully preserve it on the anterior as well as on the posterior vaginal wall. Union was made by directly suturing this torn and stretched fascia and the muscles. It depended on how much was taken up in the grasp of the needle whether one or two tiers of sutures were made, but that which was important was that the separated tissues were brought into exact apposition under control of the eye and finger. The union was made in front of the bladder or in front of the rectum, these organs being pushed back so that the needle would not enter into their structure. No matter what the operation was, whether for a slight laceration, for cystocele or for complete prolapse, the principal of procedure was always exactly the same. The different operations differed only in the extent to which the separation of the layers was carried and in the extent to which auxiliary operations were called into requisition. In cases of prolapse the only proper permanent radical procedure was operation. When the patient had entered the hospital for the purpose of a plastic operation, why not at the same time, without additional risk, perform some operation that would insure permanently the uterus in good position? He either performed the Alexander operation or made a vaginal fixation. Real vaginal fixation should be done only in women who were beyond the possibility of conception. In cases of complete pro-

lapse he sutured the uterus into the vagina after the bladder had been pushed up sufficiently, sewing the vaginal flaps directly on the uterus, using the uterus as a pelotte, thus preventing the descent of the bladder. The uterus in such cases must be fixed in the paracopal tissue; to insure its staying there it is fastened to the fascial tissue running down from the pubis. In women who might become pregnant the fixation of the vaginal flaps upon the lower part of the uterus, without opening the vesico-uterine pouch was in order.

#### Some Forms of Conjunctivitis Considered Etiologically.

DR. C. S. G. NAGEL read this paper. So-called "simple conjunctivitis" as an affection *sui generis*, has been known for many years before the days of bacteriology as an infectious disease, but its bacteriologic origin was established by the discovery of the Koch-Weeks' bacillus. Clinically, there was a severe catarrh with purulent secretion, which was sometimes difficult to diagnose from the ordinary non-contagious form. This form of conjunctivitis had been studied by accurate observers in widely separated localities. Another etiologically well-defined form of simple conjunctivitis was that caused by the diplo-bacillus of Morax-Axenfeld. This was a markedly infectious form, sub-acute or chronic, probably very frequent and widespread, under the form of a not very severe blepharconjunctivitis, affecting the angles, hence its old name of ophthalmia angularis. A third type of primary simple conjunctivitis etiologically well-defined was that caused by the diplococcus lanceolatus. This type presented itself as an eminently acute catarrh with abundant water secretion, containing here and there some formed particles and tending to heal spontaneously after a few days. Children were far more liable to the disease than adults, though with the latter the affection might be protracted or even become chronic. As severe corneal complications were very rare the prognostic importance of an early differential diagnosis as against blennorrhea was obvious. The pneumococcus being to a large degree a normal occupant of the mouth and upper air passages of man, the thought was suggested whether under certain conditions it might not become virulent and the simultaneous appearance of conjunctivitis with catarrhal condition of the air passages gave support to this view. The so-called blennorrhoeic conjunctivitis was by no means caused solely by the gonococcus. Perfectly typical cases had been seen in which no gonococci could be found, but by far the larger percentage of the severer form of blennorrhoea was due to the gonococcus. Again, another form was the pseudo-membranous conjunctivitis. Clinically, the difference between mild and severe cases was very marked. Etiologically, the latter were due almost exclusively to Loeffler's bacillus, which was also sometimes found in the milder cases, doing away with the etiological difference between croupous and diphtheritic conjunctivitis. Since the acute catarrhal forms of conjunctivitis resembled each other so much in the beginning, a bacteriologic examination was absolutely necessary in order to arrive at an exact diagnosis.

#### NEW YORK COUNTY MEDICAL ASSOCIATION.

*Stated Meeting, held Dec. 16, 1901.*

The President, Dr. Parker Syms, in the Chair.

#### Decidua Maligna.

DR. FREDERICK HOLME WIGGIN presented this specimen. The patient, after missing three menstrual periods, had a severe hemorrhage, and had passed pieces resembling those discharged in cases of uterine mole. The uterus was found to be as large as an orange. She was curetted, but this gave rise to such an alarming hemorrhage that her life was endangered, and it was accordingly decided to perform hysterectomy to save her life. After the removal of the organ the diagnosis of decidua maligna had been made. No metastases in the lungs could be detected.

DR. F. M. JEFFRIES exhibited under the microscope slides taken from this specimen, and stated that while he was unable in this instance to make a positive diagnosis he felt reasonably sure that the specimen represented an early stage of decidua

maligna, and in this view he was supported by Dr. O. H. Schultze.

#### Present Status of the Use of Tuberculin and of Products Obtained Directly or Indirectly from Tubercle Bacillus in Pulmonary Tuberculosis.

DR. E. A. DE SCHWEINITZ, chief of the Biochemie Laboratory at Washington, D. C., said that the standard tuberculin was sterilized glycerin solution of a culture of the tubercle bacilli containing the germs and their products. Experiments had been carried out on animals which were closely akin to man, i. e., on monkeys and baboons. A ring-tailed monkey and a baboon had been inoculated with a culture of human tubercle bacilli, and had been kept in separate cages. The monkey died in six weeks and the baboon in eight weeks, and all of the organs were found to be the seat of tubercular infiltrations. The opinion seemed to prevail at the present time that tuberculin should be used very carefully for diagnostic purposes.

#### Early Diagnosis of Pulmonary Tuberculosis with Exhibition of X-Ray Pictures of Diseased Lungs.

DR. J. EDWARD STUBBERT, Liberty, N. Y., was the author of this paper. He said that by early diagnosis he meant one made during what might be called the pre-bacillary stage. Out of a number of cases of incipient pulmonary tuberculosis at Liberty, 15 per cent. had been apparently cured and 63 per cent. sufficiently improved to return to their homes and become useful citizens. A slight hacking cough, with or without expectoration, slight rise of temperature, and disturbance of digestion were important early symptoms. Small pulmonary hemorrhages sometimes gave rise to no appreciable physical signs until some weeks afterward. Flattening of the clavicles, diminished expansion on the affected side, seen best posteriorly, and restriction of the movements of the diaphragm on the affected side were important physical signs in the early stage. In most instances high-pitched and prolonged expiration was present. Rales at this stage were rarely present, and the absence of tubercle bacilli from the sputum did not exclude tuberculosis. According to his experience syphilitics reacted to tuberculin. There was nothing distinctive about the anemia, which was an effect and not the cause of the disease. He had found the x-rays of value in the early diagnosis of pulmonary tuberculosis. It was best to apply the fluoroscope to the bare chest, and beginning at the apex move it downward towards the base of the lungs. In about 30 per cent. of normal chests the right apex appeared less clear than the left. If the pleura were affected it would often give rise to a slight haze. If the patient were instructed to take a long breath it would be noted that the normal side became clearer while the diseased side remained unchanged. A practiced eye could detect with the x-rays incipient foci. The restricted motion of the diaphragm on the affected side was almost pathognomonic.

#### Demonstration on Cadaver of the Surgical Anatomy of the Lung.

DR. IRVING S. HAYNES exhibited a case of long-standing empyema and directed attention to what he called the costophrenic sinus, i. e., the space between the lower border of the lung and the lower angle of the reflected pleura. This space did not exist in health. Although the text-books on physical diagnosis stated that the pleura rose much higher than the clavicle, as a matter of fact the "pleural cone" did not extend more than one-half to three-quarters of an inch above the first rib. As this part of the lung was not able to expand it followed that it was very poorly aerated.

#### Surgical Procedures for Pulmonary Tuberculosis.

DR. WILLIAM G. LE BOUTILLIER presented this paper. He said that the obstacles to be surmounted in the surgery of the lungs were both operative and diagnostic. Nitrogen gas had been introduced into the pleural cavity for the purpose of holding the diseased lung at rest, and while the method was practically free from danger it was still on trial. When there were cavities nitrogen gas was useless unless there were numerous adhesions. Suppuration in the thorax should be an indication for prompt operation.

### Treatment of Pulmonary Tuberculosis.

DR. CHARLES E. QUIMBY dwelt in this paper upon the great importance of promoting the general nutrition and improving the pulmonary circulation. He was strongly in favor of giving these patients alcohol, believing that the resulting stimulation was of the greatest importance. Aromatic bitters, mercury and arsenic were all useful medicinal agents. Hydrotherapy or vigorous dry rubbing of the skin would be found exceedingly useful, and inhalations, if properly employed, were almost always beneficial. Antiseptics seemed to have the power of diminishing the exudate.

DR. WILLIAM G. SCHAUFLER, of Lakewood, N. J., spoke of some of the every-day problems confronting the physician who had to deal with tuberculous individuals of slender means.

DR. H. P. LOOMIS was not so enthusiastic as Dr. Stubbert over the diagnostic aid rendered by the *x*-rays, for the shadows revealed by this means were so numerous as to be very perplexing. At one time, the speaker said, he had injected tuberculin into 15 cases of advanced pulmonary tuberculosis, and they had failed to give any reaction. An early physical sign of pulmonary tuberculosis was the presence of localized râles heard under the scapula when the arm was drawn forward. Heredity was not a potent factor here; the all-important one was the personal element.

DR. S. A. KNOPF spoke of the advantages of what he called the sanatorium treatment at home.

### CHICAGO NEUROLOGICAL SOCIETY.

*Regular Meeting, held Oct. 24, 1901.*

DR. HUGH T. PATRICK in the Chair.

DR. H. GRADLE presented a patient with bitemporal hemianopsia and discussed the probable site and nature of the lesion causing the symptom.

#### Myasthenia Gravis.

HUGH T. PATRICK presented a patient who was believed to have myasthenia gravis. He was a negro (not pure) 25 years of age, a cooper, and had been practically well until five years ago when the present trouble began. He first noticed weakness of the arms when at work, which soon involved the legs and was accompanied by a dull ache or feeling of intense fatigue. He early noticed that a short rest would relieve the symptoms, which would then reappear after a few minutes of work. He gradually grew worse and had been able to do no work for three years. The most striking symptom was a generalized myasthenic condition present, to some extent at all times, but enormously increased by a short period of activity. For instance, after a rest he could start off at a brisk rate and with almost a normal gait, but would rapidly weaken, and after walking about a block be compelled to come to a standstill. After a short rest he could again proceed as before. There was no particular involvement of limited groups of muscles as has been the rule in reported cases. The muscles about the shoulders and neck and the pelvo-femoral group seemed to be weaker than others, but the eye muscles, face muscles and muscles of mastication, although not vigorous, were not weaker than those of the extremities. The myasthenic electric reaction was present to a very limited degree and the deep reflexes also showed some slight exhaustion after being rapidly elicited twenty or thirty times. As the blood, urine, feces and all the thoracic and abdominal organs were normal and there were no conclusive evidences of organic involvement of the nervous system, the author was driven to a diagnosis of myasthenia gravis.

DR. C. W. LODOB inquired of the mental condition of the patient, as to whether speech was slow and intellect sluggish. Dr. Sippy asked whether there were not present some symptoms of Addison's disease and whether the tension of the pulse had been noted. Dr. Goodkine called attention to the fact that no mention was made of the condition of the patient's voice.

DR. PATRICK, in reply, stated that while the man's voice was not strong and speech was slow, the intellect seemed normal,

there was no bronzing of the skin discoverable and the pulse was soft and normal.

#### Lessons of Conus Medullaris and Cauda Equina.

DR. BERTRAM W. SIPPY, in his thesis upon lesions of the conus medullaris and cauda equina, said that the symptoms produced by their disease are well defined; but they may be readily overlooked unless one is familiar with the clinical picture produced. It is desirable both clinically and anatomically to limit the conus medullaris to the third, fourth and fifth sacral and coccygeal segments. Disease of those segments of the cord shows characteristic sensory and motor disturbances. Sensation is impaired in an area symmetrically distributed which involves the integument of the penis, scrotum, perineum, anus, inner aspect of the buttocks, and posterior surface of the thighs. The sensibility of the mucous membrane of the penis and rectum may also be dulled. If the lesion is sufficiently destructive, the muscular power of the bladder and the rectum may be seriously impaired, sexual power lost, and bed-sores may develop.

Lesions of certain fibers of the cauda equina may produce a clinical picture very similar to that of conus disease. It is extremely important to be able to recognize and differentiate the two conditions since caudal disease may often be amenable to surgical treatment. The essayist reported nine cases in which disease of one or the other of these structures was involved. The etiologic factors included focal myelitis, tumor of the conus, spinal column injury, tumor of the vertebræ, and tubercular spondylitis. The symptoms of a conus lesion were observed in one case of tabes. Autopsy was held on the case in which tumor of the conus existed. The areas of anesthesia in those cases in which the adjacent cord was involved showed a striking similarity, and did not correspond accurately to the areas previously mapped out by others who have contributed to the subject of spinal localization. The general resemblance, however, was very close.

A few of the more important points given in differential diagnosis between diseases of the cauda equina and conus medullaris are here appended. Except when due to trauma, disease of the cauda usually develops slowly, producing symptoms more or less characteristic of "root disease." Pain upon movement is first felt in the lower extremities. Later the pain becomes spontaneous and persistent with exacerbations. Subsequently, anesthesia develops. If the lesion is uniform, the cutaneous distribution of its central fibers are the first areas affected. Bladder and rectum symptoms may appear early and are usually present before anesthesia becomes pronounced. Motor weakness is present in proportion to the pressure on the motor fibers and, as a rule, does not appear until pain has become a prominent feature. The paralysis is characterized by loss of muscular tone. At onset, reflexes may be exaggerated; later, they are lost. Atrophies may develop. The electrical reactions may be altered. Decubitus has been noted.

Disease of the conus is characterized by the sensory and motor symptoms previously described. In addition, the symptoms are likely to develop rapidly. Sensation may not be disturbed alike for all qualities. The pain and temperature sense is likely to be more seriously affected than touch sense. Pain is absent. Decubitus is more likely to occur than in caudal disease. Above all, that which characterizes disease of the cauda, is pain. In a given case the absence of pain speaks directly for the conus lesion.

DR. SYDNEY KUH said that in all acute cases of segmental cord lesions low down, the diagnosis was made from symptoms as given at the outset and was very usually wrong, as the symptoms at first indicated a larger lesion than subsequently appeared. In making a differential diagnosis between conus and caudal lesions it is important to remember two symptoms, pain and disturbances of motility. In conus lesions there is less pain and more disturbance of motility, while in lesions of the cauda equina the reverse is true.

DR. BARKER asked Dr. Sippy whether in his various cases the overlapping of the terminal cutaneous nerves could be demonstrated. Dr. Sippy replied that while each area of skin

contained fibers from the separate segments of the cord, the overlapping was in the roots and not in the segments. He also stated that disturbances of pain and temperature were more sharply outlined than touch.

## Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment will be answered in these columns.]

### PRESCRIPTION WRITING, VII.

(Continued from Vol. xxvii, p. 1697.)

#### Frequency of Administration.

The rapidity with which a drug acts should govern, ordinarily, its frequency of administration. This rapidity of action is dependent to a great extent on the physical condition of the patient when the medicine is given. Medicines, however, as patients, may possess characteristics peculiar to themselves. These characteristics include their promptness in action and the length of time over which their physiologic action extends. In order to illustrate more fully, sulphonal may be referred to as an example. It is a preparation employed as a hypnotic. It varies, however, from the ordinary class of hypnotics in that it is extremely slow in producing sleep; consequently in order to obtain the best results it must be given three or four hours previous to the usual time for sleep. Owing to its tardiness in action, the dose should not be repeated in less than five or six hours. In this respect it differs from the bromid as a hypnotic, a second dose of which may be given in two or three hours if the first has not produced the desired results, the bromids being more prompt in their action than sulphonal.

Diagram to illustrate the differences produced in the amount of a drug present in the organism by alterations in the rate of absorption and excretion. The lower funnel represents the organism. A represents the condition when a drug is rapidly introduced, as by injection into a vein. In this case the drug, *e. g.*, curara, comes to be present in large quantities in the organism, and produces its full physiological effect. This is represented by the fullness of the lower funnel. And it does this notwithstanding the rapidity of excretion, which causes the drug to be quickly eliminated and to appear copiously in the urine, as represented by the fullness of the beaker into which the fluid flows from the lower funnel. B represents the condition when a drug is slowly absorbed and rapidly excreted, as when curara is given by the stomach. In this case the quantity present in the blood at any one time is very minute, as represented by the empty condition of the lower funnel. C represents the condition when absorption is rather quicker than excretion, as when a dose of morphin is given by the stomach. D represents the conditions where absorption is moderate, but excretion is interfered with, leading to accumulation in the blood, as when an active drug is given by the mouth, and the kidneys are much degenerated.

Strophanthus may also be mentioned in this connection. This preparation is very prompt in action; yet its effects as a heart stimulant extend over several hours; the frequency of its administration should be regulated accordingly.

Dr. D. R. Brower, who was among the first to employ this preparation in governing the heart's action in cases of exophthalmic goiter, states that that organ may be constantly influenced by the medicine if the strophanthus is repeated only once every eight hours.

The frequency of administration depends also upon the **Fugitive and Cumulative Action of Drugs.**

Brunton illustrates simply and concisely how the amount of any drug circulating in the body at a given time depends on the ratio of its absorption to its elimination. He takes two funnels, each provided with a stopcock and places them one above the other. The upper funnel represents the stomach, and its stopcock the vessels through which absorption takes place; the lower funnel represents the body generally, and its stopcock the channels of elimination, the chief channel being the kidneys. If the stopcock of the upper funnel is closed no fluid will be received by the lower funnel, however full the first one may be. If the stopcock of the upper funnel is slightly opened and the lower one closed, the second funnel gradually becomes full. In other words, if elimination is prevented the drug gradually accumulates in the system, even though absorption from the stomach takes place slowly, until a large quantity is taken into the body. He carries the illustration a little further and states that by opening both stopcocks, elimination will be carried on at the same rate as absorption and thus accumulation does not take place. (See illustration.)

There are certain drugs which open both stopcocks rather widely and consequently are quickly taken into the system and as quickly eliminated. Amyl nitrite is a splendid example of this class; it is quickly taken up and within twenty minutes its power is spent. Nitroglycerin acts similarly but somewhat longer, an hour or one and a half hours passing before its influence upon the circulation ceases. All the ammonium salts, the bromid excepted, are likewise quick in their action. Croton oil comes in this class. From their rapidity in action, the foregoing preparations are classed as fugitive drugs.

There are other drugs which open the upper stopcock but have no such tendency to open the lower one. In this class may be mentioned digitalis, strychnia, arsenic, the iodids and belladonna. The cumulative tendency of these preparations is well known. Each drug mentioned in this last class produces certain toxic symptoms peculiar to itself as an indication that the full physiologic limit is reached and that absorption has taken place more rapidly than elimination. Consequently, drugs in this class, being cumulative in action, when prescribed continuously for any length of time, must either be given less frequently or in smaller doses if the toxic symptoms are to be avoided.

(To be continued.)

#### Treatment of Acute Bronchial Catarrh.

Yeo recommends the following:

|                                |       |     |
|--------------------------------|-------|-----|
| R. Vini antimonialis .....     | 3ii   | 8   |
| Spts. etheris nitrosi .....    | 3iv   | 16  |
| Liquoris ammon. acetatis ..... | 3ii   | 64  |
| Tinct. camph. compos. ....     | 3ii   | 8   |
| Aquæ q. s. ad.....             | 3viii | 256 |

M. fiat mistura. Sig.: Two tablespoonfuls every three or four hours.

The following containing spirits of chloroform is sometimes employed by him to allay the cough:

|                              |           |
|------------------------------|-----------|
| R. Ammon. carb.....gr. xxxii | 2 12      |
| Tinct. scillæ .....          | m. lxxx 5 |
| Spiritus chloroformi .....   | 3ii 8     |
| Infusi senegæ q. s. ad.....  | 3viii 256 |

M. Sig.: Two tablespoonfuls every four or five hours.

#### Treatment of Atonic Amenorrhea.

The following is recommended by "Encyclopedia of Medicine" in treatment of atonic amenorrhea:

|                                |      |     |
|--------------------------------|------|-----|
| R. Tinct. ferri chloridi ..... | 3iii | 12  |
| Tinct. cantharidis .....       | 3i   | 4   |
| Tinct. guaiaci ammon. ....     | 3iss | 48  |
| Tinct. aloes .....             | 3ss  | 16  |
| Syr. simplicis q. s. ad.....   | 3vi  | 192 |

M. Sig.: One tablespoonful in water three times a day; or:

|                          |     |    |
|--------------------------|-----|----|
| R. Ext. aloes .....      | 3i  | 4  |
| Ferri sulph. exsic. .... | 3ii | 8  |
| Asafetida .....          | 3iv | 16 |

M. ft. pil. c. One pill after each meal, increased to three.

In some cases the following may be employed:

|                                       |   |    |
|---------------------------------------|---|----|
| R. Ferri sulph. ....gr. xlviii        | 3 | 30 |
| Pulv. aloes .....gr. xii              |   | 75 |
| Oleoresinæ terebinthinæ.....gr. xxvii | 1 | 75 |
| Olei terebinthinæ .....m. x           |   | 66 |

M. ft. pil. No. xxx. Sig.: Two pills after meals three times a day.

#### Treatment of Gout.

Colchicum is regarded as one of the best preparations in this condition. It is said to be much more effective when combined with purgatives or when the bowels have been previously purged. The following combination is frequently used:

|                                  |     |
|----------------------------------|-----|
| R. Vini colchici .....3ss        | 16  |
| Mag. carb. ....3i                | 4   |
| Mag. sulph .....3ss              | 16  |
| Aq. menth. pip. q. s. ad.....3vi | 192 |

M. Sig.: A teaspoonful every four hours while the pain is severe.

### Medicolegal.

**College Infirmary Not Exempt from Taxation.**—The Court of Appeals of Kentucky holds, in the case of the Gray Street Infirmary vs. the City of Louisville, that an infirmary established as an adjunct to a medical college for the purpose of making the latter more attractive to students, and to induce attendance by reason of the instruction and clinical experience received in the infirmary, and in this way to increase the profits of the professors operating the college, can not be exempted from taxation on the ground that it is purely an institution of public charity, notwithstanding that the professors in the medical college do a great deal of charitable work in the infirmary.

**Privileged Communications to Hospital Surgeons.**—Section 834 of the New York Code of Civil Procedure provides that a person duly authorized to practice physic or surgery shall not be allowed to disclose any information which he acquired in attending a patient in a professional capacity, and which was necessary to enable him to act in that capacity. Under this, the first appellate division of the Supreme Court of New York holds, in the personal injury case of Green vs. the Metropolitan Street Railway Company, that the testimony of an ambulance surgeon of a hospital as to what the party suing, who was taken in his ambulance to the hospital after an accident, told him about how the accident occurred, was properly excluded. In determining its admissibility, the burden was, doubtless, the court says, upon this party to show that the evidence was privileged. It may not have been necessary that the surgeon, in order to treat him, should obtain the information as to how the accident occurred; and it may well be said, from a medical standpoint, that it was not necessary for the surgeon to be informed of the details of the accident, but that information was necessary, upon the witness' own statement, to enable him to do some act as a surgeon, namely, to comply with the requirements of the hospital that he should ascertain how the accident occurred, in order that he might enter a history of the case upon the books of the hospital. The information he obtained from the party suing was distinctly for the purpose of making a hospital record. This evidence, which was excluded, was, therefore, the court holds, seeking to elicit information acquired in the line of the witness' duty, and to fulfill an obligation which devolved upon him in the line of his duty; and whatever may have been said by the party, therefore, can not be regarded as a voluntary statement. Under such circumstances, whatever the party may have said concerning the manner in which the accident happened can not be regarded as other than a privileged communication, being made, as it was, to enable the surgeon to discharge his professional duty in connection with a hospital case.

#### Power of Board to Employ Physician During Epidemic.

—The Court of Appeals of Kentucky holds, in Walker vs. County of Henderson, that where the entire county board of health resigned their offices because the fiscal court of the county refused to make sufficient appropriation, in their judgment, for the payment of the employes of the board, and the state board of health reappointed all the former members of the county board, and directed them to resume charge of the epidemic of smallpox and pesthouse in the county, upon their reappointment by the state board, the county board had authority to resume charge of the epidemic, and to employ physicians for the treatment of patients confined in the pesthouse. This, the court goes on to say, necessarily involved the power and right to discharge those who had been employed by the fiscal court during the interregnum, and it was the duty of the fiscal court to make fair and reasonable compensation to the persons so employed, whether they approved their employment or not. The power to determine what physicians, nurses, guards, and attendants are necessary is left to the discretion of the board of health; but the power to fix the compensation of the persons so employed, like the compensation of the members of the county boards themselves, is vested in the fiscal court of the county. But neither the county board nor the fiscal court have arbitrary power in the discharge of their respective duties. The county board could not employ persons grossly in excess of the number required. Neither could the fiscal court refuse to make compensation to persons whom the county board, in the exercise of an ordinary discretion, thought necessary, under the emergency, to employ. And the court holds that, as the physician who brought this action was regularly employed by the county board to render the services sued for, namely, to take charge of the pesthouse and treat persons afflicted with smallpox, he was entitled to be paid by the fiscal court the fair and reasonable value of such services, and the fact that the physician appointed by the fiscal court refused to surrender charge of the pesthouse to him by direction of the fiscal court, or to permit him to take charge, was no reason for refusing to pay him, as the county board had undoubtedly the right to appoint, and to continue his employment as long as services were needed in the treatment of the diseased. It was not denied that he abandoned all his business, and stayed during all the period of his appointment at the pesthouse, and was at all times able, ready, and willing to discharge the duties for which he had been employed.

### Current Medical Literature.

Titles marked with an asterisk (\*) are noted below.

New York Medical Journal, December 21.

- 1 \*The Correction of Deformities Following Osteitis of the Knee. Wisner R. Townsend.
- 2 On the Feasibility and Management of a Hygienic Cure of Pulmonary Tuberculosis Outside of Closed Sanatoria. (To be Concluded.) Charles L. Minor.
- 3 The Treatment of Abortion. Helen Hughes.
- 4 Amygdalotomy Rash. Edgar A. Forsyth.
- 5 \*Report of the Committee of Seven of the Medical Society of the County of New York on the Prophylaxis of Venereal Disease in New York City. (To be concluded.) Prince A. Morrow.
- 6 \*The Responsibility for the Recent Deaths Following the Use of Diphtheria Antitoxin and Vaccine Virus. W. R. Inge Dalton.

Medical Record (N. Y.), December 21.

- 7 \*The Cure of Chronic Bright's Disease by Operation. George M. Edebohl.

## AMERICAN.

1.—See abstract in THE JOURNAL of November 9, vol. xxxvii, p. 1266.

5.—See THE JOURNAL of December 7, vol. xxxvii, p. 1536.

**6. The Alleged Vaccine and Antitoxin Tetanus Cases.**—Dalton condemns the method of municipalities going into the business of the manufacture of antitoxin. He thinks the lesson we have principally to learn from these catastrophes is the necessity of eliminating commercialism from matters pertaining to the public health. It is false economy, to say nothing of the kind of humanity, if we do not deal with the public as with one of our own household. Boards of health should avoid scrimping economy and see that none but reliable preparations are used and should have special care for the enforcement of regulations surrounding with all possible safeguards the manufacture and sale of such articles as antitoxin and vaccine virus.

**7. Bright's Disease.**—In a former paper Edebohls advanced the proposition of the surgical treatment of Bright's disease and detailed his method. He has since operated by decapsulating the kidneys in a number of cases of chronic diffuse or interstitial nephritis and gives a table of eighteen operations. The details of some of these cases are given in the body of the article and the results in all are analyzed and discussed. The operation, he says, is not new. It has been employed by Rose and quoted by Wolff, Ferguson and occasionally by the writer as a part of the technique of nephropexy. He believes he has shown that chronic Bright's disease is curable by operation and that the present state of our knowledge does not warrant us in defining accurately the limits beyond which operation is not longer available. As a result of his experience he is prepared to operate on any case of chronic Bright's disease without incurable complications or those forbidding the use of anesthesia, and in which the probable expectation of life without operation is not less than one month. The operation is not directly and forthwith curative of Bright's disease, but it leads to a cure or improvement by establishing proper circulatory conditions.

**8. The Stomach Tube.**—Crenshaw recommends the freezing of the extremity of the stomach tube to cause temporary anesthesia in its introduction, and thus avoid nausea, gagging, etc. Freezing of the extremity of the tube has proven more satisfactory than other methods in his experience.

**10. Perineal Laceration.**—The method suggested by Norfleet is the use of anesthesia during the stormy pains. As the second stage comes on, give the patient a whiff or two of chloroform and when the head comes down enough to separate the vulva, give the chloroform to a reliable assistant and watch. When the occiput is well hooked under the pubic arch, the pain brings the extending head so far forward that the fingers feel the forehead slip under their control. At once give the word for full chloroform, and with the help of the left fingers on the child's occiput hold the head still until relaxation takes place; then slowly shell the head out by pressure on the forehead. Take plenty of time and allow the perineum to stretch as much as possible. As soon as the head is fairly out, do away with the chloroform altogether.

14.—See abstract in THE JOURNAL of November 16, vol. xxxvii, p. 1338.

**15. Methyl Alcohol Blindness.**—From a review of the literature and his own observations, Würdemann concludes that ingestion of methyl alcohol by the mouth or inhalation of its vapor has produced a sudden and in most cases complete characteristic type of blindness, tending later to partial recovery. Without a history, or long observation, it would not be possible positively to diagnose this cause, but the physician may be positive, if the case follows ingestion or inhalation of methyl alcohol with symptoms of vertigo, nausea, vomiting, etc., and with the objective appearances of immobile pupils, whitening of disk, etc., that methyl alcohol is the responsible factor.

**18. Blood Examinations.**—Kalteyer criticises the article of Deaver and Moore, published in the *Philadelphia Medical Journal* some weeks ago, in which he thinks they undervalue the importance of blood examinations for diagnosis.

**19. Hepatic Drainage.**—The importance and significance of gall-bladder disease are insisted on by Deaver and Moore, who maintain that gall-bladder surgery ought not to be relegated to

last resort procedures, but should be used when there is a tendency to recovery from the disease. If there is any marked change in the gall-bladder it is best to remove it. It is an organ of very little functional importance in the human race, and they think the day will come when the removal of the diseased gall-bladder will be considered nearly as necessary as removal of the appendix in appendicitis.

**20. Smallpox.**—The initial symptoms of recent cases of smallpox are discussed by Welch and Schamberg, who interrogated 100 patients in the Municipal Hospital of Philadelphia. The number includes 28 cases of confluent variola, 15 cases of profuse and semi-confluent eruptions, 29 eruptions of moderate severity, and 29 cases of mild varioloid. Of the 100, 22 died. Headache was the most constant of the initial symptoms. Various symptoms were present in the following percentages: Headache, 86 per cent.; chills or chilliness, 78 per cent.; backache, 70 per cent.; vertigo, 57 per cent.; vomiting, 55 per cent.; with nausea in 10 per cent. more. Chill was the first symptom in 35 cases; headache in 26; backache in 16; vomiting in 9; vertigo in 2 and general aching and pain were first in 2. In only 2 cases of the 100 was there complete absence of initial illness. One of the two admitted experiencing fatigue the day preceding the eruption. In several cases the initial illness was well marked, though not always with typical symptoms. They call attention to the fact that in a large percentage of cases admitted during the year the initial symptoms were interpreted by the physicians previously in attendance as the early manifestations of typhoid fever.

**21. Bladder-Descent and Sacculation.**—The operative procedures adopted by Shoemaker for bladder-descent in procidentia can all be done at one sitting if the patient can endure the anesthesia long enough. They are first curetting the uterus, then stripping out the hypertrophied cervix for one or two inches from the bladder in front, from peritoneum behind, and from the broad ligaments at the sides; thorough ligation of the lower lateral uterine blood supply to bring about involution of the uterus; amputation of the cervix at a point regulated by the amount of tissue hypertrophy; attaching the vagina higher up to the uterus; taking in all slack in the anterior vaginal wall, thorough repair of the perineum, with special care to pick up the lateral fasciæ. As a final step the abdomen is opened and the uterus suspended, and firmly attached to the anterior abdominal wall in women beyond the child-bearing period. In young women a light attachment is made well in front of the plane of the cornua. This, he thinks, is the most satisfactory series of operations yet devised and rarely fails to cure the procidentia and the bladder prolapse as well. In well-marked cases no one of these procedures can be omitted, though probably the suspension can be first withheld as the cases lessen in severity. He specially calls attention to the method of taking up the redundant anterior vaginal wall and supporting the bladder. The normal attachment of the anterior vaginal wall of the pelvic fasciæ is mainly at the sides, the attachment to the bladder along the median line being by loose areolar tissue which can be readily separated by the knife handle. The best method is to cut out completely all of the anterior vaginal wall down to the loose areolar tissue underlying the bladder. Inspection will show where the greatest stretching has taken place. A free incision is made directly down to the bladder wall in the median line, extending from the cervix forward as far as any widening has occurred. With the knife handle and a few snips of the scissors the bladder is then peeled off the vagina freely right and left, few vessels requiring temporary clamping, usually none. The flaps are then trimmed away on both sides with the scissors until, when their edges are brought together in the median line, all redundant tissue has disappeared. The opening may be oval or it may be broader near the cervix than at any other point, according to the location of the greatest relaxation. Two or three continuous rows of fine catgut are inserted and buried one over the other, running from before backward in the cellular tissue underlying the bladder or in the wall of that organ. They serve to obliterate dead space and firmly unite all portions of the wound surface except the

cut vaginal edges. These are best held together by a continuous fine silk suture, which alone pierces the vaginal mucous membrane. When finished, the direction of all these rows of sutures is from before backward. All bleeding is stopped by the suturing and no ligatures are required. Primary union is always obtained, as the operation is done under a continuous stream of water, and only instruments are brought in contact with the wound. Where there is much separation of the whole vagina from the pelvic fasciæ, the greatest care must be taken in operating on the posterior vaginal wall and perineum to catch the fasciæ in the stitches. The operation in these cases must always include very thorough perineal repair, the method of Emmet being preferred.

**22. Rectal Temperature in Tuberculosis.**—Braine-Hartnell concludes that: 1. In many cases the oral and axillary temperature records are untrustworthy. 2. In a few cases there is very little difference between the rectal record and the oral record. 3. The greatest discrepancy is found in the lower range of the temperature and conversely the greatest similitude in the higher ranges. 4. The rectal temperature gives in almost every case a truer idea of the amount of pyrexia. 5. If we wish to do ourselves, our patients, and our treatment justice we should insist on taking the temperature in the rectum.

**24. Antrum Disease.**—The following are the conclusions of Pierce's article: 1. That there is strong evidence to warrant the belief that in diseased antra accessory openings are more frequently found than in healthy antra. 2. That in a certain number of cases the ostium may be used to irrigate the antrum. 3. That we should in all cases, whether for diagnosis or treatment, try for the ostium or accessory openings before resorting to surgical puncture, whether through the inferior or middle meatus, the canine fossa or alveolar process. 4. That it is of no importance whether the opening through which we irrigate be the ostium or an accessory opening.

**27. Serum Therapy.**—The new antitoxic treatment of diphtheria is endorsed absolutely by Mitchell, who thinks that in it we have the means of controlling the disease. He believes in larger dosage of antitoxin. In patients over one year he gives from 2000 to 6000 units for the first dose, according to the age and the severity of the case. Under 1 year 500 to 1000 units in mild cases, 1000 to 2000 in severe cases, with the addition of 500 to 1000 in twelve hours if improvement is not marked. Of course, the most rigid aseptic precautions must be used. Experiments have shown that giving antitoxin by the mouth and by the rectum has a specific effect, but he considers that only in exceptional circumstances should it be thus given. The collected statistics of the serum treatment of tetanus show some lowering of mortality. In pneumonia the serum treatment is still *sub judice*. The reports on antistreptococcal serum are somewhat conflicting, some cases seem to respond with immediate improvement and recovery, while in others no results are obtained. This he thinks may be explained by the existence of different forms of streptococci and that the antitoxin of one may not be sufficient against that of the others. Reports of serum treatment of tuberculosis are too vague yet to be considered, and he doubts if a curative serum will be found. Plague, glanders and cholera have all been treated by serum-therapy with encouraging success.

**29. Human and Bovine Tuberculosis.**—Blackader gives first the history of the recognition of the differences between human and bovine tuberculosis, and clinical facts bearing on the intertransmission in the two forms. He thinks that the profession has unfortunately exaggerated the danger from ordinary milk. It has been misled perhaps by the frequency in which the bacilli have been reported to have existed, for many investigators have mistaken other acid-fast bacilli for true tubercle germs, and we have also been unduly afraid of a few bacilli in otherwise normal milk. There is, he thinks, little doubt that small numbers of tubercle bacilli can be introduced into the stomach with impunity, and it must be remembered also that tubercle bacilli do not develop in the milk as do many other micro-organisms, and their virulence is inhibited by

the many modes in which milk is prepared. He quotes Adami, who suggests that there may be a difference in the virulence of tubercle germs at different times which will account for some of the cases of infection described. He also, in conclusion, refers to Kossel's investigation, who found about 40 per cent. of children affected with latent tuberculosis of the glands or elsewhere. While we have given all the credit for apparent immunity in so many cases to environment and the general state of the health, it is also possible that we should consider the source from which the bacilli originally come in some cases.

**30. The Treatment of Children.**—Packard makes a number of points in regard to the difference in the medical treatment of children and adults. In the first place children can not give their subjective symptoms. We have to depend more on our own examination and we must not forget that the child is not a man cut down. Much may be learned by close observation of attitude, the character of the cry and respiration, the facies, and examination of the fontanelle as a routine matter. He points out some ways in which he thinks we are misled in estimating the frequency of certain diseases in children, for example, typhoid, where the typhoid tongue as seen in the adult is not ordinarily met with. We must also avoid falling into error in examining the chest of children, as the position of the apex beat is quite different, being higher and the second sound in the pulmonary area is louder and more clearly defined than in older persons. He also found a curious square area of dullness at the extreme left chest, posteriorly, closely resembling what has been described by Ewart as a sign of precordial effusion. He thinks the left lobe of the liver may possibly be responsible for it. The physical signs are often quite different in children and in adults; thus the cracked-pot sound can be readily developed on percussing over the healthy lung in an infant. Croupous pneumonia is another disease in which there is a great difference between children and adults, and he thinks we see much more frequently silent pneumonias and noisy pleurisies. The examination of the abdomen even offers more peculiarities than the chest. The normally large liver is one point he refers to. As regards the nervous system he refers to three points, the absence of Kernig's sign, which seems to have no significance, the slight value of the Babinski reflex and the ease in which lumbar puncture can be performed. The question of prognosis is a matter of importance. Children recover rapidly; they also die suddenly. The toxin elimination may be presumed to occur with greater facility than in the adult, and the heart has greater reserve force and reparative power than has the heart in older persons. He speaks next of the necessity of individualism in milk modification for infant food, the dangers of the routine treatment of digestive troubles, the too frequent diagnosis of intestinal parasitism, the impropriety of slitting the frenum of the tongue and the indiscriminate use of braces in rickety children, also the importance of retropharyngeal abscess, the relative easy vulnerability of the endocardium in the child, the variability of symptoms of malarial infection, etc.

34.—See THE JOURNAL of December 7, vol. xxxvii, p. 1536.

**36. Infantile Paralysis.**—The three points emphasized by Porter are: 1. The most effective treatment of deformity resulting from infantile paralysis is preventive treatment. Infantile paralysis is the cause of about 25 per cent. of the deformities that come to the orthopedic clinics. 2. Every case of paralytic deformity, however slight or severe, can be improved to some extent by appropriate treatment. 3. Simple tenotomy of the shortened tendons in these cases is of great benefit aside from the release of tension and improvement of function that result.

**37. Artificial Milk.**—The artificial milk formula recommended by Kolipinski as approximately representing the normal article, by having the proper percentage of salts and water; by being cheap, and readily prepared; the ingredient easily obtainable, fresh and sterile and the mixture palatable, is as follows: Extract of malt (syrupy), one tablespoonful; olive oil, one tablespoonful; roasted flour, two teaspoonfuls; one

broken raw egg. Beat up in a bowl or dish with a spoon or eggbeater for three or four minutes and add by degrees, while stirring, a tumblerful of pure, cold drinking water. Season with table salt. To be taken one or two hours after meals. In hot weather use crushed ice or prepare the whole in a milk-shaker. This formula may be varied to meet any conditions required. The flour may be increased or diminished. The olive oil may be replaced by some other fat or fixed oil. Unsalted butter and chocolate may be worked in. The flavor is good and the after-taste pleasant. He reports a number of cases where good results followed the use of this milk substitute.

**38. Biologic Relationship of Proteids.**—Levene in this preliminary communication reports that he has followed up Uhlenhuth's researches and finds results in accordance. They indicate that chemically differing proteids are derived from the same or closely related animals and have the power of producing similar precipitates when injected into animals. It seems probable that human milk could be used for obtaining serum for the detection of human blood. He has "immunized" rabbits with milk and found that their serums will form precipitates with milk, casein, milk albumin and beef serum, though it fails with white of egg, egg albumin, egg globulin, chicken serum, etc. On the other hand animals that had received injections of the white of the egg for two months, will form precipitates with egg albumin, egg globulin, the yolk of the egg, with chicken serum, etc., and also fail to react with the milk proteid and beef serum.

**43. Congenital Absence of Abdominal Muscles.**—The case reported by Osler is remarkable. There was complete absence of abdominal muscles, showing movements of the intestines directly on the abdominal wall, which had no resistance whatever, and allowed direct palpation of the various organs beneath. There was also associated with it thoracic deformity and cryptorchidismus, and the bladder when dilated filled the hypogastric and also the umbilical region. It was impossible to see whether the bladder was adherent to the umbilical scar as in Guthrie's case, one of the two similar ones heretofore reported. In reply to a question, Dr. Bardeen, one of the associates in the Anatomical Laboratory of the Johns Hopkins University, who has been specially engaged in a study upon the development of the muscles, writes as follows: "1. It is possible that the lack of resistance normally met with in the abdominal wall by the bladder at the time the kidneys begin to secrete urine may cause the bladder to expand rather than to empty secretions into the amniotic cavity through the urethra. 2. Under normal conditions the growth of the abdominal musculature into the *membrana reuniens*, the early covering of the abdominal cavity, is preceded by the formation of a vascular plexus supplied from above by the internal mammary, from below by the epigastric artery. It is possible that an abnormal arrangement of the blood vessels in the embryo prevented the formation of this plexus, and impeded the growth of the abdominal musculature, and that at the same time circulating disturbances gave rise to the abnormal conditions found in the bladder and ureters."

**44. The Family Form of Recurring Epistaxis.**—Osler reports cases of a special form of recurring epistaxis associated with multiple small angiomas on various parts of the skin. Two of them were brothers, showing the family relation of the disease. The father and two sisters had also been nose bleeders. One of the patients had a child who presented this defect, and a grandniece, a granddaughter of the patient's elder sister, was also subject to frequent epistaxis. The third case was of a different family, with no history of any other members suffering in the same way. The paper concludes with remarks on angiomas.

**46. Epinephrin.**—Abel has investigated the chemical behavior of epinephrin, the blood-raising constituent of the suprarenal gland, and offers, in part, the following conclusions: 1. Epinephrin in its native state easily reduces silver nitrate and other metallic salts, but fails to reduce Fehling's solution. On being treated with hydrogen sulphide or with hydrochloric acid and tin in the proper medium, or on saponi-

fication of its benzoyl or acetyl derivatives in the autoclave, it becomes an energetic reducing agent for copper solution and shows an alteration in other properties. It is not quite so easily oxidized on the addition of dilute ammonia, and is more easily crystallized. 2. The commercial preparation known as adrenalin also reduces copper sulphate. It is apparent from the analytical data furnished by Aldrich that this substance is a mixture and not a chemical individual. The proposed formula  $C_9H_{13}NO_3$ , does not coincide with the analytical data furnished by Aldrich, and no rational formula is deducible from them. It is probably a mixture of native and reduced epinephrin with traces of foreign substances rich in nitrogen. It is hoped that a better purification, together with an analysis of its derivatives, will result in a closer approximation to the formula  $C_{10}H_{15}NO_3$ , which applied to reduced epinephrin, as contained in the writer's series. 3. The series of epinephrin compounds described by the writer in previous papers, have one and all retained a single benzoyl radicle, in consequence of the incomplete saponification of the original benzoyl derivative. This could not be determined with certainty until the substance was isolated by methods which avoided the process of benzoating. The epinephrin,  $C_{17}H_{23}NO_4$ , of his former papers was therefore in reality mono-benzoyl epinephrin, and in consequence of its ability to reduce the alkaline copper sulphate it may be further designated, reduced mono-benzoyl epinephrin. Further conclusions given show that the statement of V. Furth as to the equivalents of the substance under discussion are not correct.

46. **Osteitis Deformans.**—This condition is quite thoroughly discussed, together with a report of cases, by Elting, whose conclusions are that osteitis deformans is a chronic condition of the bone, developing in middle life or later, and is of more frequent occurrence than is generally supposed. The onset is insidious sometimes in a single bone, but usually tends to be symmetrical. There is a special tendency to involvement of the tibia and femur as well as of the frontal, occipital and parietal bones. It attacks both sexes and does not appear to be related to any constitutional disease. Its etiology is not understood. It requires from five to fifteen years to reach its maximum development. It is characterized by hypertrophy and deformity of the bone involved, either with or without pain. Microscopically it is characterized by a rarefying osteitis combined with new bone formation. The duration of the disease is indefinite. It has but comparatively little influence on the general health and is not a direct cause of death. The treatment must be purely symptomatic.

47. **Tubercular Dacryo-Adenitis.**—The title of this article gives it substance in brief, but the conclusions are as follows: "1. Tuberculosis of the conjunctiva may be either ectogenous or endogenous; tuberculosis of the lachrymal gland must be hematogenous. 2. The presence of the tubercle bacillus in tuberculous conjunctivitis and tubercular dacryo-adenitis is not a *sine qua non* of the disease. In the present case, repeated examination of the matter from the ulcers of the conjunctiva failed to show the presence of tubercle bacilli, nor did inoculation in animals produce the disease. Burnett speaks of a case he observed for more than a year in which the clinical picture was one of tuberculosis of the conjunctiva, and yet he could not find a single tubercle bacillus after repeated examinations; inoculation in rabbits likewise proved negative. 3. Tubercular dacryo-adenitis and conjunctivitis may undergo cure; surgical intervention is indicated only after therapeutic and proper hygienic measures fail, since it is a universally recognized fact that tuberculosis in other parts of the body is often cured outright spontaneously, the cure being effected by a marked increase of connective tissue."

48. This article has appeared elsewhere. See THE JOURNAL of December 12, vol. xxxvii, title 160, p. 1701.

51.—See abstract in THE JOURNAL of July 13, vol. xxxvii, p. 137.

54.—Ibid., September 28, p. 852.

57. **Diphtheria.**—The summary of Dodd's discussion is that diphtheria is a practically controllable disease. The diag-

nosis can be always correctly made and with antitoxin we can save 86 per cent. of all cases, and even a much higher percentage in private practice. It should be given at the earliest possible moment, in one dose sufficient to protect the cases. It is not a medicine of last resort.

59. **Malaria After Abdominal Operations.**—Freeland calls attention to the complication of malarial fever after laparotomy in malarial districts, which may lead the surgeon to credit to serious complications what is really due to infection, and recognition of this fact will sometimes clear up very satisfactorily rather threatening cases. His conclusion is that after abdominal or other major operations in malarial districts, the patient should be put on quinin and its administration kept up until recovery from the effects of the operation.

68. **Typhoid Fever.**—Rachford reports the history of a typhoid epidemic occurring in a hotel and some adjoining cottages in a watering place in Northern Michigan. A careful study of the conditions showed defective outside plumbing leading to sewage contamination of the water supply.

69. **Degeneracy and Assassination.**—Talbot reviews the history of regicides and other assassins and would-be assassins of prominent individuals, giving portraits from the best sources, including the more recent cases of Luccheni and Czolgosz. He thinks that in most of these cases the moral imbecile element was not specially prominent, excepting in Guiteau and Clement. The frequency of facial and other stigmata is rather striking in assassins whose crimes seem to be the direct outcome of their environment. The frequency of cephalonic and allied types of skull is also striking. The uselessness of capital punishment is, he thinks, evident. As regards Czolgosz himself, he says there is no reason to believe him insane, but the logic employed to prove his sanity was not altogether scientific.

78. **Blood in Infancy and Childhood.**—Stengel and White describe the conditions of the blood found in normal infancy as regards the proportion of erythrocytes, hemoglobin, leucocytes, specific gravity, etc., and then take up the pathologic conditions. The article is too detailed to be abstracted. Illustrative cases are reported.

80. **Cadaveric Bacteria.**—Gildersleeve has investigated a number of cadavers which had been embalmed or injected and placed in protective solution for dissecting purposes. Some of these had been in cold storage vaults at a temperature of 15 F. and four had been kept in sodium chlorid vats. Bacteriologic examinations were made on the oral and nasal cavities and the skin in 8 subjects. The internal organs of the 4 subjects kept in salt solution and 19 of the cases kept in cold storage were examined also bacteriologically, both of the microscope and culture methods. Some of the results seemed extraordinary. For instance, 6 of the subjects that contained active virulent tubercle bacilli had been in cold storage between three and six months, and 2 had been in sodium chlorid vats for one to six months. The cultures were made from the caseous glands in the four tuberculous cases and staphylococcus aureus and albus found. A number of other bacilli were recognized in cultures, such as bacillus mesentericus fuscus, bacillus subtilis, staphylococcus epidermidis albus, staphylococcus pyogenes albus. These were found in the muscles of the arms and legs of three subjects which had been kept in sodium chlorid vats for 1, 4 and 6 months respectively. Lung cultures developed living bacilli in a subject who had been in sodium chlorid for four months and various other growths were obtained from the intestines, liver, spleen, gall-bladder, etc. The investigations were conducted under customary aseptic precautions and it is, as he remarks, somewhat astonishing to discover living infective organisms, such as living tubercle and staphylococcus aureus, in embalmed bodies six months after their deposition in vaults.

82. **Drainage of Peritoneum.**—Clark concludes that the peritoneum has an enormous absorbent power, being capable of taking up within an hour 3 to 8 per cent. of the entire body weight, and a number of solid particles are carried in a re-

markedly short time from the peritoneal cavity through the diaphragm into the mediastinal lymph vessels and glands, and thence into the blood circulation. They are often largely transported as free bodies, swept along by the lymph currents, but later the leucocytes act as the carriers. There is, normally, a force in the peritoneal cavity which carries fluids and foreign particles toward the diaphragm regardless of posture, though it may be aided or retarded by gravity. The micro-organisms introduced into the peritoneal cavity are greatly reduced in number within the first hour, both by intra-peritoneal destruction and their rapid absorption into the general system. There is, therefore, no possibility of limiting free infectious matter to any part of the peritoneal cavity by mechanical means. Vigorous streptococci which remain behind develop within six hours a repellent or destructive quality of leucocytes, and the lethal combat is, therefore, inaugurated and well under way before drainage, as ordinarily employed, can possibly exercise any good effect. In many cases, therefore, where surgical drainage is employed the patient recovers in spite of, and not because of it. A moderate amount of even virulent organisms, carried by the blood to the lungs, liver, spleen, kidneys, gastro-intestinal tract, and bone-marrow, may be destroyed or eliminated without the least harm to the patient, whereas, if the same amount of infectious matter is detained about a surgical field in the abdominal cavity, or stagnates in a dependent pocket, they may generate myriads of others, and thus overwhelm the patient. Drainage, therefore, as ordinarily employed, is superfluous in many cases and even dangerous. The rational method is to remove all possible debris or infectious matter by thorough irrigation and then leave one liter of salt solution—0.6 of 1 per cent.—in the abdominal cavity, in order to promote and hasten natural drainage, supplemented by an enema of a liter of salt solution given while the patient is well under anesthesia in the Trendelenburg position. Under this plan the patient is greatly stimulated, shock is minimized or averted, the urinary excretion is greatly increased, and thus toxic matters are more easily eliminated without irritation to the kidneys or bladder; peritoneal infection is more quickly eliminated while yet minimum in amount; thirst is alleviated, or entirely prevented; intestinal peristalsis is promoted, and tympanitis less frequent. The early action of the intestines evacuates infectious matter thrown out into the canal by the blood-vessels of the villi. All these factors combine to reduce mortality after abdominal sections, to decrease the pain, discomforts and complications of the first forty-eight hours, and hasten the recovery. Peritoneal infusions may be dangerous in cases of ascites accompanying surgical lesions, which indicates that the natural peritoneal drainage is already deficient; therefore, to add an additional burden through the saline infusions is certainly not advisable. In general purulent peritonitis he believes that gauze packing is indicated in apparently few cases and often where it can be used, painstaking technique will reduce the necessity. He would use it in appendicitis, when there is infiltration of the adjoining tissue and peritoneum and in localizing collections of pus in the pelvis. Such cases are specially those for incision and drainage through the vagina. Suture of intestine, excision of fistulous tracks leading from the intestines to the abdominal wall, and purulent peritonitis are also conditions in which drainage through the genital tract may be advisable.

**99. Vocal Nodules.**—Knight has had the opportunity of seeing vocal nodules developing almost under his eye, and it has suggested to him several perplexing questions. The growth appeared rather suddenly after over-exercise of the voice, and treatment was ineffective until vocal exercises were tried together with inhalation of adrenalin chlorid—1-5000—when there was some very apparent improvement. He theorizes somewhat in regard to the cause and suggests the possibility of minute localized hemorrhages or of fibrous contraction of certain bundles of fibers; the overstrain of the cords might lead to an effort of nature to fortify the region of their exercise by throwing out new tissue. The idea that

attrition of the vocal bands is accountable for the nodes seems to him untenable for the reason that during phonation space must remain between the bands in order to permit the blast of air. Moreover, the node often has its origin, as in this case, on the upper surface of the band. If his theory is correct, the obvious conclusion is that a faulty method of phonation is generally induced by some anomaly in the upper air tract, and can be overcome only by restoring the latter to a normal condition. In excising or destroying the nodule we remove the result and not the main cause of the difficulty.

**101. Bacteria in the Nose.**—Iglauer, who has examined nasal cultures from a number of cadavers and who has studied the literature, comes to the conclusion that the normal nasal mucus contains bacteria, but that they can not be so abundant as we would suppose from the number of bacteria inspired, for the following reasons: The surface over which the bacteria is scattered is rather large. From measurement he finds it about 154 sq. cm. in the nose and 25 in the nasopharynx. Some bacteria must reach the nasopharynx from which they are swallowed and digested. The flow of mucus and serum together with gravity tends to carry away the germs and the nasal mucus is not a good culture medium. Last and most important, the organisms which have reached the nose are expelled by the ciliated epithelium with great rapidity, and recent work seems to show that nasal epithelium has bactericidal power. The practical conclusions he deduces are: "1. It is advisable to sterilize the vestibule of the nose before operating. 2. After operation, the nostril on the operated side should be closed with a piece of cotton to act as a filter. 3. Plugging of the nasal cavity after operations is, as a rule, inadvisable, as it tends to retain the nasal secretions. 4. Nasal wounds do not heal by first intention, owing to the presence of bacteria. This also explains the occurrence of secondary hemorrhage. 5. Fever after operations and the few deaths recorded, have probably been due to the presence of pathogenic micro-organisms in the nose."

**108. Hydrocyanic Acid Disinfection.**—Fulton and Stokes give further results of their experiments with hydrocyanic acid as a disinfectant. The chemicals used are potassium cyanid, concentrated sulphuric acid and water, in the relative proportion of 1, 1.5, and 2.25. The amount of gas used was expressed in the terms of cyanid—25 grams of cyanid per 100 cubic feet of enclosed space. They connected three jars, placed at suitable relative elevations, by siphon tubes. The requisite amount of cyanid was placed in the lowest and largest jar, the intermediate jar contained water, and the upper the concentrated acid. The lower of the two siphons was automatic, and actuated by a definite height of liquid in the upper jar. It did not, therefore, operate until the last few ounces of liquid was being delivered from the upper jar into the intermediate one. By this means the operator had time to leave and close up behind him and there is no danger that the destructive chemicals will escape from their containers. The sides and floor of the room used for the experiments were covered with tar paper. The doors and windows were weather-stripped and two shelves were built across the window, and here the cages containing animals and insects were placed for easy observation. The exact moment when effervescence began was noted in their experiments and correctly timed observations were recorded. The animals and insects were exposed in tubes with cotton stoppers or in wire cages, the amount of defensive covering being always noted. House flies were killed in two to four minutes after effervescence began in the cyanid jar; wood-eating white termites in ten minutes; white rats and guinea-pigs in the same time. Roaches were killed during eight or ten minutes if confined in a tube with one inch of cotton plugging; in nineteen minutes to one hour if protected with two to nine inches of cotton plug. Bedbugs were killed in fifteen minutes. Mosquitoes, culex, were dead in two and one-half minutes in an aquarium jar covered with cheesecloth and rapidly when protected with one and two inch plugs. Other animals like the ox louse, black ant, rats, mice, etc., were readily killed. Rats exposed in cages succumbed in a very few minutes, though

after thirty seconds' exposure they could be revived. Gas tested by test-paper quite a distance from the keyhole of the door was found to be rapidly diffusible. Bread, butter and milk were exposed for twenty-four hours to the action of hydrocyanic acid in vapor three times denser than that sufficient to destroy animals and then fed to rats and no poisonous effects were observed. He thinks the advantages of the gas for disinfection are numerous. It is highly diffusible, has no injurious effect on wood work, metal, textile fabrics, paint or foodstuffs, and rapidly escapes when doors and windows are opened. It does not require special attention to openings, all that is necessary being that the gas should have free access. Of course, it is dangerous to man, but not unmanageable, and after each experiment the room was entered instantly for the purpose of removing the insects and animals, the only precaution being to suspend respiration. It is specially useful in military hygiene, disinfection of hospital tents and mess tents, which can be done by merely closing the ventilators while the disinfection is being carried on and throwing up earth to close the opening between the tent and the soil. Latrines can also be fumigated in this way. While the suggestion to use this agent is not likely to be readily accepted on account of the general belief in its deadliness, the authors believe that cyanid is about as amenable to human purposes as many other substances of less ill-repute.

**115. Tetanus Antitoxin.**—Reasons for the relatively small incidence of tetanus and fatalities in the recent St. Louis epidemic with diseased antitoxin are given by Fisch as follows: 1. The use of tetanus antitoxin. He believes in tetanus antitoxin. Nearly 60 bottles of the contaminated antitoxin serum were dispensed and anti-tetanic serum was injected in a great number of cases even before the symptoms appeared. None of them developed tetanus. In one case where the incipient muscular stiffening was observed recovery followed the use of tetanus antitoxin, but none of the cases in advanced stages of tetanus recovered. 2. The fact that the contaminated serum producing the disease contained just enough toxin to prove fatal to a certain weight of human tissue. Clinical experiments showed that .10 c.c. of serum was a fatal dose for 300 grams of guinea-pig weight, and it was concluded by comparing the average weight of children, etc., that 10 c.c. of the contaminated serum contained the approximately fatal dose for human beings weighing 50 pounds, showing that the susceptibility to tetanus toxin in man is nearly equal to that of the guinea-pig and about half that of the horse. If there had been spores or the bacilli in the serum very few of the patients would have survived. 3. The observation that a great number of immunizing doses of this serum had been administered per os, and therefore did not exert their toxic effect. In at least fifteen cases the development of tetanus was prevented by the administration of serum by the mouth. In no case was any bad effect observed. According to Fisch we have known all along that the toxin of tetanus is not absorbed by the gastro-intestinal mucous membrane. It is a fact that active tetanus bacilli are not rarely inhabitants of human and animal intestines. It is, however, established that the membranes of very young animals or infants may be intoxicated in this way, and as explanatory of this, a histologic observation is offered. In the newborn and for a short time after birth the secretion of mucus by the gastric mucous membrane is not present. The epithelial cells of the newborn appear uniformly protoplasmatic, are free from granules and sharply defined towards the free surface. Only later, in some places can small masses of mucus be demonstrated. This formation of mucus appears in certain foci and is in the beginning restricted to the most superficial layers of the protoplasm of the cells. It is possible that the absence or slight extent of mucin-formation is favorable to the absorption of the toxin. He does not recommend this method of immunizing, however, as a general practice.

**116. Cleft Palate.**—According to Bartlett, who reviews the various methods of palatal surgery, Brophy's operation is for its purpose the best procedure at our command, inasmuch as it is the only one which gives to the bony arch its proper breadth.

and the only one which can by reason of the slight hemorrhage caused and the little time required, be performed upon a poorly-nourished child at a period when perfect vocalization must be secured or the golden opportunity be forever lost.

**120. The Skull and Its Contents.**—This article is surgical, bearing on the question of operation for injuries, and Earles sums up that we should use the trephine or chisel in every case of severe injury to the head, carefully examine the soft parts, and, if injured, repair at once. If this is not done at the time of injury, then as soon after as circumstances will permit, in the hope of preventing secondary sclerosis. When sclerosis has become established thoroughly excise the diseased area, substituting healthy and comparatively non-irritating union for the old diseased condition, making certain that the offending area is the one removed.

**127. Alcohol.**—The conclusions reached by Storek are that small quantities of alcohol favor salivary and gastric digestion, but large quantities inhibit all the digestive functions. Alcohol, whisky, gin and brandy are less harmful to digestion perhaps than are malt liquors and wine, but the continuous use of alcohol in any form, even in small amount, is liable to prove detrimental to digestive processes. In persons of weak digestion alcohol is harmful unless given very well diluted. It should never be given when the stomach is empty. It is valuable in disease, requiring no primary assimilation, it yields force readily to an exhausted system and in small quantities promotes appetite. It is well to bear in mind that the purer the whisky or brandy the less destructive it is to the digestive processes. According to Dujardin-Beaumetz, the toxic effects of alcohols increase with the sum of their atonic weight, with the exception of the highest and lowest. Finally, it is true, as Wood says, that: "Science in no way contradicts the experience of every *bon vivant* that the small doses of alcohol increase, and larger amounts interfere with, the activity of digestion."

**135. Dandruff.**—According to Dyer dandruff is a product of seborrheic dermatitis, an infectious and inoculable disease, though we do not as yet know the special germ. The application of resorcin in bay rum 3 to 5 per cent. is, in his opinion, an absolute cure. He has had no patients who did not recover under this treatment if they left brushes alone. The first instruction he gives to a dandruff patient is to throw his brush into the fire and not get another until he tells him, and he does not tell him until he finds the scalp free from dandruff. Resorcin sometimes gives a yellow tinge to light or gray hair. The addition of salicylic acid solution will prevent this. Where there is any reason to forbid the use of resorcin, chloral hydrate in a 2 to 5 per cent. solution may be used, or the naphthol solution in the strength of a scruple to the ounce. He believes that dandruff may have serious consequences. It often starts colonies in other parts of the body, produces seborrheic conditions in the wings of the nose, and may even aid in the production of malignant disease.

## FOREIGN.

The Lancet, December 7.

**Pure Urea in the Treatment of Tuberculosis.** HENRY HARPER.—In this second article on the subject Harper reports seven cases treated with urea with remarkable success. He thinks it exerts a specific action on tuberculosis, quite as marked as that of mercury in syphilis, salicylate of sodium in rheumatism and iodid of potassium on bronchial asthma. The urea used was a synthetic product and he suggests that it is an interesting question whether that derived from animals would have the same effect. "Cases suitable for the administration of urea are: 1. Circumscribed pulmonary tuberculosis of the lung in which the sputum exhibits abundance of bacilli and only a limited number of cocci. 2. Enlarged tuberculous glands situated on any part of the body. 3. Tuberculous pleurisy (here in my cases urea acted like magic). 4. Tuberculous laryngitis. 5. Lupus. 6. Tuberculosis of the peritoneum with fluid in the peritoneal cavity. 7. Hydrocephalus in children. 8. Tabes mesenterica or carrean. Cases which are unsuitable are: 1. Pulmonary tuberculosis where cocci pre-

dominate, practically covering the whole field of the microscope, and the tubercle bacilli exhibit a short stumpy appearance, the typical Koch's bacillus being scanty. 2. Acute miliary tuberculosis with a high temperature (103 F. or over). 3. Gastritis. 4. The last stage of tuberculosis where the patient is dying. 5. When the patient has a temperature over 101. Mode of administration: To carry out the intensified method a beginning should be made with small doses of from 10 to 15 grains thrice daily, gradually increasing them up to 40, 50 or 60 grains as a maximum. Practically this amounts to  $\frac{1}{2}$  per cent. of artificial urea added to the normal quantity circulating in the blood." The way he came to prescribe urea was from the suggestion offered by the apparent immunity of gouty individuals. He asked himself if gouty salts are antagonistic to tuberculosis; is it not possible to administer these to tuberculosis? He quotes Dyce Duckworth, Harris, Beale, Weber and others in favor of this view. He believes that natural immunity has not received due recognition and he thinks there is almost a parallel in this respect between typhoid fever and tuberculosis as regards the greater susceptibility among country residents moving into town. The drift of medical opinion to-day is to ignore heredity and over-value contagion, assuming that every human being is vulnerable to tuberculosis. He suggests that the race has become somewhat immune by heredity. He has never yet seen any harm come from the administration of urea, and has obtained the best results from 40 to 50 gr. doses three times a day. The highest dose he has reached has been 70 grs. three times a day, which practically equals one-half the total quantity of urea excreted by the average healthy man. The notion current in all the textbooks that urea is a substance to be gotten rid of, is not in accordance with his experience. He now believes that uremia or anything like it can not be induced with urea, for here we have the toxalbumins to be reckoned with. The gain of flesh coincident with the ingestion of urea is an obvious fact demanding an explanation, and he suggests that it is nutritive and supplements the food. In all his cases where death followed after administering urea, mixed infection was the predominant feature, and he has come to believe that failure to respond to this drug is a differential test for true tuberculosis and mixed infection.

**The Pathogenesis of Fibrous Hyperplasia.** E. H. COLBECK.—The different forms of fibrosis, post-inflammatory, compensatory, fibrosis of mechanical congestion and senile fibrosis, are noticed in detail by the author. The first depends upon the increased functional activity due to increased nutrition. As regards the second, he thinks the treatment of fibroid degeneration is unscientific and incorrect. Overgrowth of tissue can not be called degeneration. The fibrosis of metabolic congestion is also a disturbance or loss of control over food supply and the relative increased nutritive stimulation of fibroid tissue cells. Senile fibrosis is also to be considered as a loss of control over nutrition, and while he has excluded the action of the nervous system in his consideration he believes it has an important influence. With the decline of functional activity there is no doubt a diminution of nervous influence, so that, with respect to their claim on nutritive supplies, the degraded functioning cells in their vegetative condition would be pitted against the purely vegetative connective-tissue cells; hence, the increased relative proliferation of the latter.

December 14.

**On Duodenal Ulcer and Its Surgical Treatment.** B. G. A. MOYNIHAN.—The subject of duodenal ulcer, acute and chronic, is gone over by Moynihan, who finds that it is generally situated in the first portion of the duodenum and may affect all ages, but is more frequent in men than in women. The symptoms are apt to be obscure and the co-existence of gastric and duodenal ulcer is in his opinion more frequent than generally believed, and may confuse the diagnosis. The cardinal symptoms are pain, which is generally experienced an hour or so after eating and referred to the epigastrium, or the right hypochondrium, or indefinitely to the upper part of the abdo-

men, hematemesis, which is an occasional and rather erratic symptom, and melena, which was observed in 9 of Perry and Shaw's 60 cases. Examination of the stools for small quantities of blood is so unusual that we must admit that this symptom may be more frequent than generally supposed. The complications are hemorrhage, perforation, cicatricial contraction, and induration and their sequelae, periduodenitis and cancer. As regards treatment he reports two cases of perforation from acute ulcers, one treated by gastro-enterostomy by the Murphy button, the patient dying, and the other treated by stiteling up the opening and drainage, with an uneventful recovery. Speed is important in this operation, the details of which are given at some length. He gives a tabulated analysis of 40 cases of operation for perforation. When subacute or chronic perforation leads to periduodenal or subphrenic abscess it should be opened in front if periduodenal, and if subphrenic, through the anterior or lateral walls of the abdomen, or through a low intercostal space. If perforation is discovered it should be closed by suture, and a drainage tube should be passed down to the abscess cavity and left in for two or more days. A case is reported. When pain and gastroenterorrhagia or enterorrhagia are persistent and disabling, gastro-enterostomy should be performed, to rest the part and permit the healing of the ulcer. Cicatricial contraction and induration or periduodenitis are to be treated on the same principles by gastro-enterostomy. Four cases are reported, all of which recovered.

**Experimental Hemoglobinuria Caused by a Bacterial Toxin.** CHARLES TODD.—In this preliminary communication Todd reports the results of experiments with bacillus megatherium on guinea-pigs and other animals. He finds it produces megatheriolysin which resembles the toxins of diphtheria and tetanus in being extra-bacillary, being unstable at ordinary temperature, but less so than tetanolyisin. Heating seems to destroy it rapidly. There exists apparently an anti-body in normal serum, exercising a very considerable anti-hemolytic action which is increased on heating. Filtered cultures produce hemoglobinuria in guinea-pigs to a very marked extent, but not so much so in rabbits, when injected intravenously. He remarks that the fact that a widely distributed organism, which has hitherto been regarded as practically non-pathogenic, is capable of forming products bringing about in susceptible animals such profound blood-changes, is of the greatest interest, and though this bacillus may have no causal relation to any pathologic condition in man, the results obtained are suggestive in connection with the pathology of such diseases as blackwater fever, paroxysmal hemoglobinuria, and pernicious anemia.

British Medical Journal, December 14.

**Nephrectomy, Nephrolithotomy and Lithotomy.** T. R. JESSOP.—The subjects discussed by Jessop are nephrectomy in children, of which he does not speak very encouragingly, and says that he can not but emphasize the lack of confidence he feels in recommending operation in children suffering from malignant growths. Still he suggests the comparative safety of intraperitoneal inspection of the kidneys on the first suspicion of a growth, as it is only by early detection and prompt removal that we can hope to improve on our former unsatisfactory results. As regards nephrectomy in adults he is inclined to believe that the lumbar operation will be preferred in those cases in which sepsis is known or supposed to exist, and for nephrectomy in which the growth is of recent origin and of small size, while the larger renal tumors will be attacked from the front with more prospect of success in proportion to our increased knowledge and attention to details in the operation itself, and to our ability to avert death from shock. The statement that nephrectomy in the adult gives more encouraging results than in children must be qualified in that it applies not to the immediate but only to the ultimate result. The immediate operation is not the worst thing in children, it is the future outcome of the cases. The author admits change of heart as regards operation for nephrolithotomy and he now holds it to be of value as compared with his former opinion. He specially commends the method of withdrawing the

kidney from its bed and exposing it outside, then splitting it into two symmetrical halves by incision from the convex border through to the pelvis and returning it to its natural position after having passed three or four catgut sutures deeply through the substance of the organ tied with just enough force to arrest the bleeding. This plan is adopted from Dr. Henry Morris, and he has used it for the removal of stone in five cases with the most satisfactory results. He thinks it is sure not only to remove the stone, but makes the operation safer and more effective. For vesical calculus he favors suprapubic operation and litholapaxy, using the latter whenever practicable, irrespective of the age of the patient, and the former when existing conditions forbid the other or seem specially to favor a shorter and severer operation.

**The Sanatorium Treatment of Pulmonary Tuberculosis.** R. W. PHILIP.—The sanatorium treatment, the system, open-air exercise, rest, diet, skin hygiene, medication, site of sanatorium, general condition of patient and stage of the disease are all discussed by the author. He believes that the constitutional condition has been hitherto too little considered in the treatment of pulmonary tuberculosis. The sanatorium treatment is physiological. It can be practiced at home or at any place where there is sufficient accommodation and appreciation of what is necessary, but there are grave difficulties in the way of home treatment. Success will depend upon the thoroughness with which the physiologic conditions are fulfilled, which, therefore, depends upon the physician. He recommends the establishment of some sort of tuberculosis colony where the convalescent patients might contribute by working for the common good, remaining all the time under medical supervision.

## Queries and Minor Notes.

### IS ABORTION JUSTIFIABLE IN THE INSANE PREGNANT?

CINCINNATI, Dec. 18, 1901.

*To the Editor:*—A young woman shortly after marriage, was discovered to be mentally unsound, the character of her mental condition being akin to paranoia. Her husband is a neurasthenic with a bad heredity; her mother has paranoia and has been in the asylum 35 years; father was an inebriate. The woman is pregnant. Whether pregnancy will affect her mental condition favorably or unfavorably is uncertain; probably it will affect it very little either way. But there is little doubt the child would be a degenerate.

Now, would it be justifiable to produce an abortion to prevent the birth of such a child, or could such a procedure under the circumstances be considered criminal?

P. Z.

Ans.—It would be criminal.

### PARTNERSHIP WITH UNLICENSED AND NON-DIPLOMAED BROTHER.

MICH., Dec. 23, 1901.

*To the Editor:*—Will you kindly decide the following question: We have here a physician registered under the laws of this state who has taken his brother into partnership with him and passes him off as a licensed physician. This brother has not received a certificate from the State Board, nor has he a diploma from a medical college. Would it be considered proper for reputable physicians to consult with this doctor whose partner is an irregular practitioner?

G. H. W.

Ans.—The case is one for the attention of the State Board of Examiners, and we would suggest that our correspondent write to the secretary, Dr. B. D. Harrison, Sault Ste. Marie, and report to him the facts. It would be a good plan for a reputable physician to treat his brother practitioner who may not be doing just as he ought, in a liberal and brotherly way. Petty jealousies are often the result of misunderstandings; possibly there is some misunderstanding in this case. In any event if our correspondent will do with his fellow practitioner as good old Ben Franklin would have done in a like instance, there will be a better feeling between the two physicians in this Michigan village.

### IS METALLIC PLATE USED IN TREPHINED SKULL?

LAKE CITY, COLO., Dec. 19, 1901.

*To the Editor:*—Will you kindly let me know through the columns of THE JOURNAL or otherwise whether modern surgeons

put in silver or gold or other kind of plate when a portion of the skull is removed after fracture? Has it ever been done? If not commonly done what are the objections to it?

J. G.

Ans.—The most obvious objection would be the danger of infection from without from an exposed foreign body in that situation, unless the skin healed on the plate. It has been done, but we do not see it recommended now. Transplantation of bone, replacement of bone button, or an osteoplastic flap from the external table are sometimes resorted to. The insertion of silver or gold foil over the exposed brain or meninges is sometimes performed.

### MOOD OF "FIAT CAPSULA."

U. S. MARINE BARRACKS, WASHINGTON D. C., Dec. 4, 1901.

*To the Editor:*—One of the events of the week is the arrival of THE JOURNAL at the Dispensary here. Even a layman like myself can always find a great many articles by which the gray matter may be improved. I am, let me state, old-fashioned. In your issue of November 30, of this year, under the heading of "Therapeutics," you say "The word *misc* means, when translated, mix thou." It does. It is a command issued by the physician to the pharmacist. You proceed to say that the word "*Fiat*—meaning may be made—is in the subjunctive mood." Is it? Is not *fiat* more properly of the imperative mood? Does the doctor, in the first instance, say mix thou, and in the second, you may (if you like) make the substance into, say, six capsules, or if that number does not just suit you, please yourself? Does the doctor mean that he has no choice as to whether the patient gets his medicine in powder, capsule, or pill form? I am open to correction, but in my humble opinion the prescriber intends to be just as emphatic in the second case as in the first.

As to the parsing of the sentence "*fiat capsula*," a rule of Latin syntax, which I quote from memory, is as follows: Verba substantiva ut sum, fio, existo; verba vocandi passiva ut nominor, appellor, dicor, vocor, nuncupor et iis similia, utriusque eisdem casus habent. Brevi esse laboro, obscurus fio.

The word *spiritus* which you mention in the first paragraph, leads me to ask which is the correct form—*spiritus frumenti*, or *spiritus frumentis*.

Respectfully,

C. P.

Ans.—1. The verb *fiat* is, as was stated in THE JOURNAL of November 30, in the subjunctive mood, but with an imperative force. The imperative forms of the verb would be *fi* in the singular, and *fi*te in the plural.

The reason why the more regular verb *facere* was not used in the imperative, as *fac*, "make thou" like *misc*, "mix thou" is probably because *facere*, "to make," was used also in the sense of "to administer," "to give; for instance, Cicero says: *Medicinam alicui facere*, with the meaning "to administer medicine to a person." Hence, *fac pilulas xii* could also mean "give 12 pills," and to avoid ambiguity the old physicians were obliged to use the semi-deponent and irregular *feri*, "to become, to be made."

2. *Spiritus frumenti* is correct, the nominative being *frumentum*.

## Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE PRACTICAL MEDICINE SERIES OF YEAR-BOOKS. Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Issued Monthly under the General Editorial Charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. Vol. I. General Medicine. Edited by Frank Billings, M.S., M.D., Head of Medical Department and Dean of the Faculty of Rush Medical College, Chicago. With the Collaboration of S. C. Stanton, M.D., October, 1901. Cloth. Pp. 270. Price, per volume, \$1.50. Chicago: The Year-Book Publishers.

GYNCOLOGICAL PATHOLOGY. A Manual of Microscopic Technique and Diagnosis in Gynecological Practice for Students and Physicians. By Dr. Carl Abel, Privat-Dozent, Berlin. Translated and Edited by Samuel Wyllis Bandler, M.D., Adjunct Gynecologist to the Beth Israel Hospital, New York. With a Chapter on Embryology of the Female Genitalia and the Pathological Growths Developing from Embryonal Structures. Illustrated by 100 Engravings. Cloth. Pp. 237. Price, \$2.50. New York: William Wood & Co., 1901.

PROGRESSIVE MEDICINE. VOL. IV, 1901. A Quarterly Digest of Advances, Discoveries and Improvements in the Medical and Surgical Sciences. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia. Octavo, handsomely bound in cloth, 400 pages, 13 illustrations. Price, per annum, in four cloth-bound volumes, \$10.00. Philadelphia and New York: Lea Brothers & Co.

PHOTOGRAPHIC ATLAS OF THE DISEASES OF THE SKIN. A Series of 80 Plates, Comprising More Than 100 Illustrations, with Descriptive Text, and a Treatise on Cutaneous Therapeutics. By George Henry Fox, A.M., M.D., Clinical Professor of Diseases of the Skin, College of Physicians and Surgeons, N. Y. Part VI. In 16 Portfolio parts at \$1.50 each. Philadelphia and London: J. B. Lippincott Co., 1901.

**PERU—HISTORY OF COCA**, "The Divine Plant" of the Incas, with an Introductory Account of the Incas, and of the Andean Indians of To-day. By W. Golden Mortimer, M.D., Fellow of the New York Academy of Medicine. With 178 Illustrations. Cloth. Pp. 576. Price, \$5.00. New York: J. H. Vall & Co. 1901.

**OFFICIAL LIST OF PHYSICIANS AND SURGEONS Who Have Received Certificates of Registration under Public Act 237, Laws of 1899, Michigan.** By Authority of State Board of Registration in Medicine. November 1, 1901. Paper. Pp. 88. Sault Ste. Marie, Mich.: News-Record Press.

**A COMPLETE EXPOSE OF EDDYISM OR CHRISTIAN SCIENCE, and the Plain Truths in Plain Terms Regarding Mary Baker G. Eddy, Founder of Christian Science.** By Frederick W. Peabody, Member of the Boston Bar. Paper. Pp. 68. Price, \$0.25.

**MEDICAL AND SURGICAL REPORTS OF THE BOSTON CITY HOSPITAL.** Twelfth Series. Edited by Herbert L. Burrell, M.D.; W. T. Councilman, M.D., and Charles F. Withington, M.D. Paper. Pp. 201. Boston: Published by the Trustees. 1901.

**WATER AND WATER SUPPLIES.** By John C. Thresh, D.Sc. (London), M.D. (Victoria), D.P.H. (Cambridge). Third Edition. Revised and Enlarged. Cloth. Pp. 527. Price, \$2.00 net. Philadelphia: P. Blakiston's Son & Co. 1901.

**A MANUAL OF CLINICAL LABORATORY METHODS.** By John Benjamin Nichols, M.D., in Charge of the Clinical Laboratory, Garfield Hospital. Illustrated. Cloth. Pp. 303. Price, \$2.50. New York: William Wood & Co. 1902.

**THE LIFE OF PASTEUR.** By René Vallery-Radot. Translated from the French by Mrs. R. L. Devonshire. Vols. I and II. Cloth. Pp. 292 and 336 respectively. Price, \$7.50. New York: McClure, Phillips & Co. 1902.

**REPORT OF THE SURGEON-GENERAL OF THE ARMY to the Secretary of War, for the Fiscal Year Ending June 30, 1901.** Paper. Pp. 354. Washington: Government Printing Office. 1901.

### New Patents.

Patents of interest to Physicians, December 3 and 10:

- 687,978. Sterilizer. Arthur Castle, Rochester, N. Y.
- 688,163. Head-bandage. Bettie P. Fields, Mason, Tenn.
- 687,994. Producing chemically pure hydrochloric acid. Eugen de Haen, List, near Hanover, Germany.
- 687,748. Automatic distributor for powders. Per B. Harje, Karpalund, Sweden.
- 687,750. Artificial limb. Max Hield, Milwaukee, Wis.
- 688,102. Reducing and deodorizing residues. Walter P. Lincoln, and M. S. Greenbaum, Louisville, Ky.
- 688,188. Tampon. Anthony E. Magoris, Binghamton, N. Y.
- 688,131. Obtaining ianthone and ionone. Ferdinand Sembritzki, Holzminden, Germany.
- 35,373. Design, hot-water bag. John B. Miller, Chicago.
- 688,499. Exercising device. Wm. G. Bell, Sharonhill, Pa.
- 688,581. Massage instrument. Otto Bihlmaier, Brunswick, Germany.
- 688,458. Stereoscopic x-ray apparatus. Eugene W. Caldwell, New York City.
- 688,604. Producing blood-albumen. Max Dietrich and A. Langer, Berlin, Germany.
- 688,463. Making caustic alkali. Hans A. Frasch, Hamilton, Canada.
- 688,465. Movement cure apparatus. Ernst F. Goransson, Stockholm, Sweden.
- 688,734. Hernial truss. George V. House, Mount Vernon, N. Y.
- 688,311. Artificial limb. Lowell E. Jepson, Minneapolis, Minn.
- 688,688. Syringe. Walter H. Humphrey, New York City.
- 688,695. Hernial truss. Louis Ropers, Lincoln, Ill.
- 688,354. Bandage or compress. Siegmund B. Sonneborn and H. Beigel, Baltimore, Md.
- 688,371. Suspensory. George A. Wieland, Duluth, Minn.
- 688,804. Suspensory. George A. Wieland, Duluth, Minn.
- 35,417. Design, vaccination shield. Joseph A. Steinmetz, Philadelphia, Pa.

## The Public Service.

### Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Dec. 12 to 18, 1901, inclusive:

John M. Banister, major and surgeon, U. S. A., from duty at the U. S. Military Academy, West Point, N. Y., to accompany troops on the transport *Burford* sailing from New York City, about Jan. 15, 1902, to Manila, P. I., where he will report for assignment in the Division of the Philippines.

Walter K. Beatty, contract surgeon, leave of absence from the Department of Colorado extended one month.

Charles E. B. Flagg, captain, asst.-surgeon, U. S. A., member of a board at Fort Grant, Ariz., to determine the fitness of certain officers for promotion.

Bower E. Himes, contract surgeon, previous orders revoked: he is relieved from duty at Fort Keogh, Mont., and will proceed to his home, Mill Creek, Pa., for annulment of contract.

William F. Lipplitt, Jr., captain, asst.-surgeon, U. S. A., honorably discharged by the Secretary of War as major and surgeon, Vols., only, to take effect Dec. 31, 1901: he is relieved from duty in the Philippines, and on the expiration of his present leave will report for duty at Fort McHenry, Md.

Alexander N. Stark, captain, asst.-surgeon, U. S. A., from Fort McHenry, Md., to the U. S. Military Academy, West Point, N. Y., to relieve Major John M. Banister, surgeon, U. S. A.

Francis M. Wall, contract surgeon, from the Division of the Philippines to Fort Thomas, Ky.

### Navy Changes.

Changes in the Medical Corps of the Navy, for the week ending Dec. 21, 1901:

Asst.-Surgeon John B. Buchanan, appointed from Nov. 23, 1901. Medical Director R. C. Persons, commissioned from Nov. 3, 1901. Medical Inspector E. H. Green, commissioned from Nov. 3, 1901. Medical Inspector L. G. Heneberger, commissioned from Oct. 29, 1901.

P. A. Surgeon H. H. Haas, commissioned from Dec. 28, 1900. P. A. Surgeon C. A. Crawford, commissioned from June 1, 1901. P. A. Surgeon E. Thompson, commissioned from April 19, 1901.

Asst.-Surgeon D. G. Beebe, resignation accepted, to take effect Nov. 30, 1901.

Medical Director A. L. Gihon, retired, died Nov. 16, at New York City.

Asst.-Surgeon E. Davis, died Nov. 15, at East Las Vegas, New Mexico.

### Marine-Hospital Changes.

Official list of the Changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended Dec. 19, 1901:

Surgeon H. R. Carter, granted leave of absence for ten days from Dec. 26, 1901.

P. A. Surgeon W. G. Stimpson, detailed as inspector of unseviceable property at the San Francisco quarantine station.

P. A. Surgeon J. B. Greene, to proceed to Malone and Rouses Point, N. Y., for special temporary duty.

Asst.-Surgeon S. B. Grubbs, granted leave of absence for nine days from December 26.

Asst.-Surgeon J. F. Anderson, relieved from duty in the office of the U. S. Consul at Liverpool, England, and directed to return to the United States.

Asst.-Surgeon L. D. Fricks, granted leave of absence for thirty days from December 16.

Asst.-Surgeon W. C. Hobdy, to proceed to Jacksonville, Fla., for the purpose of making a physical examination of the Local Inspector of Hulls at that port.

Asst.-Surgeon Carroll Fox, assigned to duty in the office of the U. S. Consul at Liverpool, England, relieving Asst.-Surgeon J. F. Anderson.

Asst.-Surgeon Jos. Goldberger, granted leave of absence for fourteen days from December 21.

Asst.-Surgeon J. S. Boggess, ten days' extension of leave of absence granted by bureau telegram of December 10, revoked.

Hospital Steward F. S. Goodman, relieved from duty in the Hygienic Laboratory, and directed to proceed to Key West, Fla., and report to medical officer in command for duty and assignment to quarters.

Hospital Steward M. H. Watters, relieved from duty at Boston, Mass., and directed to proceed to Washington, D. C., and report at the Bureau for orders.

### Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Dec. 20, 1901:

#### SMALLPOX—UNITED STATES.

- California: San Francisco, Dec. 1-8, 1 case.
- Georgia: Elberton, Dec. 12, 12 cases.
- Indiana: Evansville, Dec. 7-14, 2 cases.
- Maryland: Baltimore, Dec. 7-14, 1 case.
- Massachusetts: Dec. 7-14, Boston, 60 cases, 6 deaths; Cambridge, 1 case, 1 death; Medford, 1 case.
- Minnesota: Winona, Dec. 7-14, 2 cases.
- Nebraska: Omaha, Nov. 30-Dec. 14, 22 cases; South Omaha, Nov. 30-Dec. 14, 40 cases.
- New Jersey: Camden, Dec. 7-14, 10 cases; Jersey City, Dec. 1-15, 23 cases; Newark, Dec. 7-14, 26 cases, 3 deaths.
- New York: New York, Dec. 7-14, 10 cases, 2 deaths.
- Ohio: Ashtabula, Dec. 7-14, 3 cases; Cincinnati, Dec. 6-13, 6 cases.
- Pennsylvania: Allegheny City, Nov. 30-Dec. 7, 1 case, 1 death; Lebanon, Dec. 9-16, 25 cases; Norristown, Dec. 7-14, 2 cases; Philadelphia, Dec. 7-14, 125 cases, 8 deaths.
- Tennessee: Dec. 7-14, Memphis, 7 cases; Nashville, 1 case.
- Utah: Salt Lake City, Dec. 7-14, 2 cases.
- Vermont: Burlington, Dec. 7-14, 4 cases.
- Washington: Tacoma, Dec. 1-8, 1 case.
- West Virginia: Wheeling, Dec. 7-14, 1 case.
- Wisconsin: Fond du Lac, Dec. 3-10, 1 case; Green Bay, Dec. 8-15, 11 cases.

#### SMALLPOX—FOREIGN.

- Austria: Prague, Nov. 16-23, 7 cases.
- Brazil: Pernambuco, Oct. 15-31, 72 deaths.
- Canada: Quebec, Dec. 7-14, 25 cases; St. John, Nov. 30-Dec. 7, 16 cases; Windsor, Dec. 7-14, 1 case.
- Colombia: Panama, Dec. 2-9, 25 cases.
- France: Paris, Nov. 23-30, 2 deaths; Rheims, Dec. 16-20, 2 cases.
- Great Britain: Glasgow, Nov. 29-Dec. 6, 4 cases; London, Nov. 23-30, 427 cases, 23 deaths.
- Russia: St. Petersburg, Nov. 16-23, 1 case.

#### YELLOW FEVER.

Mexico: Vera Cruz, Nov. 30-Dec. 7, 8 deaths.

#### PLAGUE—FOREIGN AND INSULAR.

- Philippines: Manila, Oct. 12-25, 5 deaths.
- India: Bombay, Nov. 19, 181 deaths; Karachi, Nov. 10-17, 49 deaths.

### TREATMENT OF CHRONIC MYOCARDITIS.\*

JOHN H. MUSSER, M.D.  
PHILADELPHIA.

The condition to which attention is directed in this communication is one of chronic myocardial disease, a fibroid condition if you please, which results from, or is secondary to, sclerosis of the coronary arteries. It should be called coronary artery endarteritis, or chronic endarteritis of the coronary arteries with secondary myocarditis. This is the form which is to be kept in mind in discussing the details of treatment. It is not possible to pick out from the mass of humanity the individuals or class who are likely to be affected with this condition so as to apply measures of prevention. The patients only present themselves for treatment after the condition has become well established and our efforts are to be directed towards delaying the progress and alleviating the sufferings of the patient during the attacks of angina or dyspnea, or other myocardiac symptoms, which attend upon it, and adopting measures that will make the occurrence of these attacks infrequent. The treatment divides itself into hygienic management and medicinal management. The latter in turn depends much upon the associated lesions which are present in the case, and the amount of organic change that has taken place in the heart muscle especially.

When a case, which presents this condition of coronary endarteritis, or chronic myocarditis, comes before us, there is no question more important or so difficult to decide as that of how much rest will be required; whether he shall abstain entirely from business cares, or only partially. This depends largely upon the patient's station in life and must be decided from the standpoint of each individual case. Shall he give up his occupation entirely, or devote a few hours daily to it, while avoiding much exertion, and take the remainder of the day for rest? Much depends upon the proper decision of these questions, for the greater part of the cases are men of great responsibilities, which can not readily be given up, and our judgment of the matter means a great deal to them, as they are often busy men, who have active interests in educational, mercantile, political and other affairs. Our judgment must depend upon the conditions which we find to be present in the individual case, not only the condition of the heart and the vessels, but of other organs and the general state of the patient's

health. Important to note are his excretory functions, his ability to digest sufficient food, his recuperative powers, and also the nature of his work. All these things must be considered, but we must be especially guided by the actual amount of the local sclerosis and the ability of the patient to recuperate after exercise, or the amount of fatigue that appears after ordinary exertion. In order to determine what changes must be made in his life, all the circumstances in the daily life of the individual must be weighed and given proper consideration. We must pass in review all the acts of the day, the character of his food, the power of digestion, and if there is any marked change or not in the gastric powers, and modify the character of the food and its quantity to suit the case. If dilatation or hyperacidity exists, this must be taken into account. If any tendency to gout or rheumatism is present due attention must be given to correct it. The character of the urinary secretion is to be frequently examined into for this purpose also. In short, we must be guided by all these considerations in our solution of the problem of diet. Then again, we must study the peculiarities of individual cases as to the effects of particular articles of food. Next, we must take up the question of bathing. Shall the patient be allowed to continue, if accustomed to take a cold bath in the morning, or shall he take some other form of bath in preference? Would he be benefited by the shock of cold shower or douche, or shall he be subjected to the relaxing effects of a warm bath? The answer to this, in any case, must depend upon the actual condition of the myocardium, and whether or not fatty degeneration is present, and, on the other hand, the condition of the general circulation. In the great majority of cases, the warm sponge bath at night, followed by moderate friction, will be sufficient, and all that can be safely done in the way of bathing. The saline baths as employed at Nauheim may be employed in many cases. In a few cases the steam bath, or hot-air bath, is useful, especially if the gouty or rheumatic diathesis be present. These baths may be given two or three times a week, according to effects observed. The clothing must also be looked into, but this and other hygienic matter of importance must be passed over in order to take up the question of treatment.

As regards the medicinal treatment of myocarditis, if we can settle upon a definite cause for the endarteritis or coronary artery disease, such as syphilis, this will to a large extent indicate the line of treatment to follow. In other cases, the treatment must be determined by the arterial condition, whether or not high or low arterial tension is present. In the treatment of the latter, digitalis in large or small doses, spartein, strychnin and other direct cardiac stimulants are useful. If there

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. Thomas Hunt Stucky, Leon L. Solomon, and N. S. Davis, Jr.

is high arterial tension present, it is the custom to give remedies which lower blood pressure, and those who give such remedies see delightful results from nitroglycerin, strontia salts and other agents which lower blood pressure. The fact is too often overlooked that some general measures also reduce blood pressure, such as purgatives. Many of these cases are benefited by salines given early in the morning, every day or two. In cases with high arterial tension, the use of magnesium sulphate every morning, or some similar salt, gives marked relief.

There are cases of chronic myocarditis, secondary to coronary artery disease, where we can not satisfy ourselves, or determine by ordinary physical signs, the exact state of the heart muscle—cases in which the condition may only be inferred from reduplication of the second sound of the heart and the state of the veins, where there is no dilatation of the heart walls. Nor, on the other hand, can we determine the existence of any hypertrophy, particularly that occurring with high arterial tension. There are cases of this kind in which the dyspnea is marked, with considerable arrhythmia, in which we can not obtain any special evidence from the condition of the vessels that would indicate high arterial tension. These form a class of cases, in my mind, in which I feel that digitalis will be of benefit.

Now, as to the treatment of one or two of the clinical manifestations of myocarditis. The first we shall consider is angina pectoris. The treatment of the paroxysm is so familiar to all that it needs no argument concerning it; but the treatment in the interval should be considered. When in the course of myocarditis the attacks of angina occur, then it becomes necessary to modify the habits of life and to avoid too much active exertion. As remedial agents we use nitroglycerin, or iodid of potassium, and avoid digitalis and other preparations which increase the pressure of the blood. In using nitroglycerin, it should not be given in ordinary doses of a drop of the solution every two or three hours, but it should be rapidly increased until we get the physiological effects of the drug. Cases in the practice of the speaker had taken up to half a dram of the 1 per cent. solution three times a day with the greatest benefit. It is of this point which we wish to speak especially in the treatment of angina pectoris. In these cases in a fair measure it is in our power to prevent cardiac hypertrophy from occurring. The patient must be put upon a lower scale of life as regards exertion; as soon as he begins to live upon the same scale as an ordinary individual, with ordinary blood pressure, he will have attacks of angina pectoris.

The dyspnea of myocarditis is of two forms: That occurring with dilatation of the heart, the other with asystole. In one case, the dyspnea is almost constant, increasing into paroxysms in times of special excitement or exercise. The second form is that which occurs only in paroxysms, in attacks which take the form of sudden edema of the lungs, with chest oppression, and all the appearances of shock—pallor of surface, cold extremities, more or less anxiety, the expectoration of frothy material. Upon auscultation of the chest the bronchial tubes are found filled with râles, and on auscultation of the heart the most interesting conditions are found—arrhythmia and asystole. It is often impossible to recognize any murmur on account of the râles in the chest. These cases are frequently mistaken for pulmonary conditions. Such a case must be treated first as a case of shock. We must relieve the pulmonary edema that has taken place; we must actively stimulate the

heart and improve the circulation. Dry cupping of the chest and external hot applications bring the most speedy relief. There is no better remedy than morphin, administered hypodermically in small doses, for the relief of the patient. The speaker relied upon it, together with strychnia and nitroglycerin, where there is apparently a condition of high arterial tension; where this is not present morphin and strychnin alone will tide over the difficulty until the danger is past. Where there is venous stasis and lowered blood pressure, the use of digitalis and ordinary stimulants will be sufficient to overcome the condition. The speaker knows of nothing which required closer study and care in the application of therapeutic measures than these cases of chronic myocarditis. We must study not only the cardiac or cardiovascular condition, but also that of all the organs and structures of the body in order to treat them with satisfactory results and afford them the greatest amount of relief and comfort.

#### DISCUSSION.

DR. HENRY BEATES, Philadelphia, said that he had listened with interest to the remarks of Dr. Musser, because so far as the medical treatment of the class of cases described was concerned, experience had placed him in a position of direct antagonism to the views just expressed. He entirely agreed with the speaker in so far as the general hygienic management of these cases was concerned, and with that part of the communication which had a special reference to prophylaxis, but when the medical treatment of these cases is considered, personal experience with chronic myocarditis consequent upon endarteritis, whether it be of the coronary artery or elsewhere throughout the arterial system, compels him to take an exactly opposite position from the essayist, and to advocate the use of circulatory stimulants as a general principle, and the avoidance of circulatory depressants. The point he desired to particularly make clear was, that there is a great accumulation of blood in the venous system and a relative diminution of the volume of blood in the arteries. Hence, in these cases where the symptoms of distended veins, pallor, dyspnea, diminished renal secretion, etc., obtain, there is not increased arterial tension, but, on the contrary, marked diminution thereof. The theory advanced by the essayist is that, under these conditions we must administer large doses of cardiac depressants and notably, nitroglycerin. Let me direct attention to a strange fact; when nitroglycerin is employed in these conditions for relief, the paroxysms generally are aggravated, and still larger doses in extreme cases are then administered. The result is that the symptoms are all intensified, and when a serious collapse threatens, then the administration of these depressants is abandoned, and, in their place, is administered what should have been in the first instance, namely, digitalis, ammonia, strophanthus and alcohol. It is submitted that whenever there is increased venous congestion, other things equal, there must be lessened arterial tension. The physiology of this matter is too large a subject to be introduced in this discussion, and it must be left with the simple statement. In the intervals between the attacks of angina pectoris, there is a condition of more or less constant dyspnea, rapid irregular intermittent cardiac action, with distended veins, venous hyperemia of the kidney, cerebral venous hyperemia, or, if you choose, arterial ischemia, and a digestive tract which, by reason of the distended veins, is incapable of performing the functions of absorption. If these conditions are met by the use of remedies that stimulate the action of the arteries, not the heart especially, then these cases of chronic myocarditis will be greatly relieved and they may live in comparative comfort and the paroxysms described and the fatal result postponed for from many months to several years. He said this after an experience of many years with large numbers of cases which had been treated unsuccessfully with the use of cardiac depressants; these especial cases have been restored by the continued use of arterial stimulants to a condition of

comfort which, from the clinical phenomena presenting at the time they first came under observation, there was no reason to believe could be accomplished. The explanation of this mode of treatment is based upon the fact that it is the function of the arteries to propel the blood, and if the profession will ever realize the fact that each artery is practically a heart for the area it supplies, it will be understood that arterial tension for that area can not possibly exist while the veins of the same region are in a state of turgescence.

The remedy he had found efficient for restoring lost circulatory equilibrium, whether it be local or general, was that one derivative of digitalis manufactured by Merck, and known as digitalin Germanic. None other will do it. The ordinary official preparations of digitalis can not be relied upon to accomplish this with any degree of certainty, because the different constituents of the crude drug are possessed of varied physiologic power. Then again, they exist in a given specimen of the true drug in such varying proportions and are differently soluble in the menstruum used for the preparation, that it is impossible to state, until the actual therapeutic value of the given preparation is determined, whether the property desired is possessed or not. For illustration, alcohol dissolves certain derivatives and therefore the tincture of digitalis will contain principles which the infusion does not. He had, after careful comparative study, abandoned commercial digitalin, digitoxin, digitalin verum, in a word, all but the one especially designated. This is made by precipitating a principle from the infusion of digitalis by the use of tannin; this is subjected to a chemical process, which can not at this time be described. The administration of this especial derivative is safe, and other things equal, will invariably restore circulatory equilibrium. It should be exhibited in doses varying from one-fourth to one-half grain, from three to six times daily as especial conditions indicate. In conclusion, experience had shown that the conditions described called for the administration of arterial stimulants and especially the remedy named. Arterial depressants as a rule should never be employed. There are conditions in which rarely it is necessary to employ both, for reasons which familiarity with the physiology of circulation will make plain.

DR. S. E. SOLLY, Colorado Springs—He regretted that the essayist did not go further and mention the effects of climate upon these cases, as patients are often advised to travel and many are sensitive to climatic change. This is especially true when the change is to a high altitude. Patients with chronic myocarditis or coronary disease sent to Colorado often improve because of the lowered arterial tension which the diminished barometric pressure produces. They may do well as long as they remain quiet and avoid active exercise, but even slight exertion at a high altitude is much more dangerous for them than at sea level. On this account he did not believe that, as the rule, high climates are suited to these cases. At the same time he had been surprised to find how much many of them could do without showing ill-effects, going up Pike's Peak for instance. Of course this was accomplished without exertion as they were carried up in the train, but they did it without being injured. Though some cases reside permanently in Colorado with benefit and comfort, yet the safe rule is to send these patients to less extreme climates of moderate altitude where the air is also sunny but more equable in temperature, and while not absolutely damp has more moisture in it than that of the higher altitudes.

DR. O. T. OSBORNE, New Haven, Conn., thought that if the two speakers from Philadelphia could be brought together in consultation over a case that there would be very little difference between them in the treatment of chronic myocarditis. The special preparation of digitalin mentioned has not been sufficiently studied, as it is of recent introduction and more experimentation is needed to decide whether it is a vaso-dilator or vaso-constrictor.

DR. BEATES—It is a vascular constrictor.

DR. O. T. OSBORNE—Our information upon the effects of these remedies has been recently much extended by the discovery that there is a vaso-dilator element in the adrenal gland and

it gives a stimulus for more careful study of all cardiac drugs. In the condition under consideration, we sometimes need a vaso-constrictor and sometimes a vaso-dilator, but we almost always need morphin. Nitroglycerin given over a long period is also of much value. He had often thought that the cases that occur after the age of 45 years, when the thyroid gland is beginning to atrophy, may be really due to a decrease of the functional activity of the thyroid. In fact he had found in many cases that small doses of thyroid extract have been productive of good effects. He had also used potassium iodid with satisfactory results, but believed that he had observed better continued results from the use of the thyroid in these cases.

## THE INFLUENCE OF SOME OF THE COMMONER DRUGS UPON THE GASTRIC FUNCTIONS.\*

BOARDMAN REED, M.D.

PHILADELPHIA.

The following observations were made in my laboratory on five persons employed in an office building in Philadelphia during February, March and April, 1901. None of them complained of their stomachs. They were not invalids or under medical treatment, though some of them realized that they were not in robust health.

In every case the stomach contents were extracted by a Kuttner rubber bulb, one hour after an Ewald test breakfast, with one exception, when the time was fifty minutes. The contents were filtered before being examined. No attempt was made to empty the stomach completely, since to do this adds needlessly to the discomfort of the procedure and does not add any important reliable information. The motor power of the stomach can be measured much more accurately and conveniently by other means.

All the persons thus experimented upon had been eating ordinary diet, and were directed to continue with the same food and under like conditions otherwise, during each period of observation.

For the sake of convenience the results of the various tests have been arranged in the form of tables, which are here given:

It is first of all noteworthy, that of these five average persons, all engaged actively in earning a livelihood and none of them complaining of any stomach symptoms, only two, Cases 1 and 2, had an approximately normal gastric secretion and peptonizing power. Case 4 showed some sourness from fermentation and far too low a figure for the combined HCl, which is a fairly accurate measure of peptonization. Other tests pointed to deficient motility in this case. The total acidity percentage of HCl was, however, about normal. The two others had less than the normal amount of HCl; indeed, a marked deficiency of it.

The tincture of nux vomica was chosen for the first test, since it is one of the most active and bitter, as well as one of the most commonly administered, of all our so-called stomachic and general tonics. The results might at first be considered rather contradictory, since in two cases (Nos. 1 and 2) the use of the remedy before meals for five days produced a lessened secretion, while in the other three there was a decided increase. This outcome is especially interesting for the reason that the depressing effect took place in the two persons whose gastric juice was practically normal, persons, therefore, who did

not need medicine for their stomachs; and the stimulating effect occurred in the three who exhibited manifest gastric faults, one of them a somewhat impaired motor power, and the two others a marked lack of HCl. Five cases are too few, of course, to warrant any sweeping inferences, but there has been an abundance of clinical observations which show that any organ which is functioning healthfully already, is likely to be injured by drug stimulation.

The next test, to ascertain the effect on the gastric glands of administering HCl regularly for a time, yielded remarkably striking results, which being in complete harmony with clinical observations reported of late from various parts of the world, must be accepted as conclusive.

Every one of the five persons who took 10-drop doses of dilute HCl in water after meals for a period of five to six days, experienced a very positive stimulant action upon the glands whose function it is to secrete HCl, and the two virtually normal stomachs whose glandular apparatus was depressed by the nux vomica, not only regained what had thus been lost, but had their secretion carried to a higher level than before; higher, indeed, than normal. In one of these the HCl reached a point which may be considered hyperchlorhydria. And this resulted in the short period of five days from doses of dilute HCl, which many writers regard as altogether too small to be effective.

But the mistake has frequently been made of overlooking the exceedingly important fact, that this remedy, be-

sides its occasional palliative action when given in very large doses, by aiding a deficient gastric juice directly in the work of peptonizing proteids in the stomach, in the presence of a sufficient amount of pepsin or propepsin, possesses also the property of exerting positive stimulant action upon the glands by which HCl is secreted. This point was emphasized by me in a paper read before this Section three years ago.<sup>1</sup> In that paper I referred also to communications upon the same subject by Hemmeter in this country, as well as by Wegele, Riegel, Reichmann and Mintz in Germany.

All the above-named authorities have become convinced that the administration of HCl as a medicine tends gradually to increase the secretion of the same acid by the stomach. In some of my cases in which there was an almost entire absence of such secretion, the administration of dilute HCl in doses of five to ten minims after meals for long periods, as three to six months continuously, has been followed at last by a restoration of the secretion to the normal amount.

The fact that small doses of HCl, in conjunction with other appropriate treatment, may produce this restorative effect, in many cases—probably in most cases in which atrophy of the glands has not developed—may be considered as fully established. It has been also proved that even small doses of HCl may set up hyperchlorhydria in normal stomachs, or aggravate it, when that condition already exists.

Three of the persons experimented upon took 5 grains of scale pepsin (that made by Parke, Davis & Company), for periods of from seven to seventeen days. They were Cases 3, 4 and 5, those whose stomachs, it will be observed, were least normal. These tests of pepsin were made about a month after finishing with the other ones, though in Case 3, the person finding HCl so beneficial, had taken a dose or two nearly every day during the interval, and Case 4 had taken it with an approach to regularity during the same time. Case 5 had taken no HCl for fully three weeks when she began the use of the pepsin after meals. None of the three took any HCl during the experiment with pepsin. Without these explanations one might infer from the results shown in the tables above, that an active preparation of pepsin, so far from exerting any restorative influence, tends to produce a lowering effect upon the gastric secretion, and possibly it may in some cases. But it will be noticed that in the trial upon the person (Case 5), who took no HCl for several weeks before the pepsin test, there was virtually no change in the amount of the HCl secretion and digestive work done before and just after the week during which pepsin was administered.

In the other two cases the falling off in the secretion of HCl and in digestive work during the period that pepsin was administered and HCl not administered, may, therefore, no doubt, be properly attributed to the withdrawal of the acid, which we now know to be our most active gastric stimulant.

It is a fair inference from these experiments that pepsin given as a digestant, though known from a large number of clinical observations to be a helpful palliative under certain conditions, does not, at least, like numerous other glandular products of the body, tend to augment the natural secretion of the same by its prolonged use.

An additional series of experiments was carried out in April, 1901. In each of five different persons, three of

whom had a deficient secretion of HCl at the time, the following experiments were made, and in the case of one of them the same were repeated a week later: Small cubes of coagulated egg albumin of the same size were prepared and one of these introduced into each of four test tubes with 3 c.c. of the filtered stomach contents taken up one hour after an Ewald breakfast. Nothing further was put into tube 1; to tube 2 two grains of scale pepsin were added; to tube 3 one drop of dilute HCl, and to tube 4 both pepsin and HCl were added. All the tubes were then placed in an incubator and the temperature kept as nearly as possible at 38 C. The results of these tests need not be reported here in detail, yet a summary of them may be instructive:

In two only of the six tubes to which pepsin was added was there shown any more rapid solution of the egg than where the chyme alone was allowed to act. The analysis in one of these two cases previously made had shown somewhat more than the normal proportion of HCl—free HCl, .094; combined, .080—and the other revealed a marked deficiency.

In the other five experiments, while in every case except one there was free HCl present though deficient in amount, there resulted a distinct retardation of the digestive process in all the tubes in which pepsin alone was added to the mixture of chyme and egg.

The addition of HCl alone produced a doubtful result in one case, i. e., there was no appreciable difference between the amount of digestion in the tube with only the stomach contents and that in which HCl was added. In three of the cases it helped more or less, though in one only slightly. In the case of one person with whose chyme the test was made twice at an interval of one week, the result was each time a positive retardation of the digestive process. The analysis of a portion of the same chyme showed the first time T.A. 50, with free HCl .065, and the second time T.A. 46 and free HCl .065, combined HCl .058—certainly not an excess of secretion.

The addition of both the HCl and scale pepsin produced a more rapid solution of the egg in each of the six trials. Test-tube experiments in digestion have, of course, much less value than when the remedies are administered to living persons. Many of us have been led to consider pepsin especially a very mild and safe remedy, which is not likely to do harm even if it can do no good. Acting on this principle, I recently prescribed moderate doses of pepsin for a very delicate lady who would not permit a test of her stomach contents to be made, and the result was a severe aggravation of her symptoms. She then informed me that she had once before experienced a similar result from the same medicine.

The increased digestive power exhibited by all the six specimens of stomach contents when pepsin and HCl were both added, even in persons the action of whose gastric juice was notably retarded by either drug alone, is curious and most interesting. It shows the folly of dogmatizing too positively as to just what part any particular element of a secretion plays in the observed effect, and the wisdom of humbly endeavoring to imitate Nature as nearly as possible in concocting remedies to supply a deficiency in the work of any organ. It is very likely that if we should combine pepsin, HCl and rennin with water and the other minor ingredients of the gastric juice in the proportions usually found in the human stomach, we should obtain a remedy of much greater effectiveness than any now in use for weak digestion.

The results of the foregoing experiments would seem to point toward the following conclusions:

1. The Place of Hydrochloric Acid in the Treatment of Diseases of the Stomach. By Boardman Reed, M.D., JOURNAL A. M. A., 1898, and Int. Med. Mag., October, 1898.

1. Perfectly normal stomachs are probably in the minority in large cities, especially among persons employed indoors.

2. In stomachs which are normal or approximately so, the digestion may be injured by a simple bitter tonic, taken even for a short time.

3. Quite moderate doses of HCl administered as a medicine may prove effective in hypochlorhydria, but are likely to do harm to normal stomachs and certain to aggravate hyperchlorhydria.

4. Pepsin rarely produces any good result when given alone, even to persons with weak digestive power, and often then retards the digestion of albuminoids.

5. Pepsin and HCl given together much more frequently do good than either administered singly.

I desire to acknowledge my indebtedness to Dr. C. B. Worden, my assistant, for his efficient services in carrying out many of the details of the above described experiments.

### TREATMENT OF CHRONIC ROUND ULCER OF THE STOMACH.\*

G. FUETTERER, M.D.

CHICAGO.

Medical men have always had an inherent desire to put therapy on a rational basis. This feeling could not be downed any more than truth itself; knocked down, it would rise again to renewed effort. *Cessante causa, cessat effectus*, is the never-dying war cry that rings in our ears from generation to generation. Such thought leads me to commence my paper on treatment of ulcer of the stomach with a consideration of its etiology.

A normal stomach does not digest its own tissues, neither as a whole, nor in part, and when self-digestion does take place it involves circumscribed portions, showing that there are agents contained in the gastric juice which act in harmony with certain local causes that lessen the resistance of parts of the wall of the stomach, allowing a partial self-digestion, which leads to the formation of a so-called round, peptic, perforating, chronic ulcer of the stomach. So we have two causes, one in the gastric juice, which is uniformly distributed through the interior of the stomach, and the other, which, at least during life, is always localized, and, therefore, only permits a part of the wall of this organ to become digested. Both causes have received due consideration, and still we can not say that our views concerning the etiology of ulcer of the stomach are sufficiently cleared to allow a good understanding of the factors at work and their comparative value. Hyperacidity, or rather hyperchlorhydria, of the gastric juice on one side, and local circulatory disturbances from vasomotor irregularities, embolism, atheroma, thrombosis or hemorrhage, on the other, whatever their causes may be—traumatism, chemic and thermic influences—are considered as the main factors bringing about the formation of gastric ulcers, and no doubt they all are of greatest importance. But if we consider the attempts which have been made by experiments on animals to show the value of those different factors, we are forced to admit that we have not yet arrived at a full understanding. If we review literature on this subject, we find that many successful attempts to produce artificially ulcer of the stomach in animals are recorded. Hydrochloric acid has

been brought into the stomach; chemic, thermic and traumatic lesions of the mucosa have been made; blood vessels have been ligated; hemorrhages, embolisms and necroses have been produced; the nervi vagi have been cut; the duodenum was ligated, and the reports tell us that typical ulcers were produced.

I have repeated many of these experiments without being able to convince myself of their reliability. I also have succeeded in producing ulcers which in many instances had quite the appearance of ulcers as they occur in men, but a more thorough macroscopic and microscopic examination soon convinced me that they were healing ulcers, granulations covering their basis, and an epithelial covering growing towards their center from all sides. The gastric ulcer in man has no tendency to heal. It is chronic in character, and, therefore, we can not allow the statements of those to go unchallenged who have been satisfied with observing general macroscopic appearances, merely stating the presence of ulcers, without giving a detailed macroscopic and microscopic description.

Silbermann<sup>1</sup> has wisely considered another important factor, hemoglobinemia. Destroying hemoglobin by injections of hemoglobin and pyrogallie acid, and then causing embolisms, mechanical injuries, etc., he has produced ulcers, leading to hemorrhage and perforations, which would lead us to think that, although he does not report microscopic findings, he has produced genuine ulcers.

I have made a great many experiments, but, considering that my subject is treatment of ulcer, I shall not go into detail. I have resected mucous membrane of the stomach, removing one-third of the volume of blood of the animal right after operation. Result: After two weeks the defect was healed.

Again, mucous membrane was resected, one-third of the blood volume removed right after operation, and again as much as possible, without killing the animal, three days later. Result: After two weeks an ulcer that had the appearance of ulcer in man, but fresh granulations at its basis, and microscopic examination showed that an epithelial covering was growing from all sides towards the center of the ulcer; it was in the process of healing. Then, the same experiment was made, and the animals were allowed to live a week or two longer. Result: The ulcers had healed.

*Conclusion.*—A lack of volume of blood does not promote the formation of an ulcer.

After this, the same experiments were repeated, and the hemoglobin was destroyed by frequent injections of pyrogallie acid. Result: Typical ulcers which macroscopically and microscopically showed no tendency to heal. These findings compare well with our clinical experience in gastric ulcer of man.

In younger years we find gastric ulcer in combination with chlorosis, and in later years with different forms of secondary anemia, from lack of digestion or assimilation, atheroma, thrombosis, embolism, hemorrhage, thrombosis, malaria and syphilis. The general factor, anemia, or rather hemoglobinemia, is to be considered most important, while the others, the local causes, are of more secondary consideration. On this basis we must establish our plan of treatment. I feel that I can make the dictum that an ulcer of the stomach can form only when there is a certain amount of hemoglobin lacking, and that it must heal when the hemoglobin percentage is increased to a certain amount.

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. Thomas Hunt Stucky, Leon L. Solomon and N. S. Davis, Jr.

Based on these conclusions, I proceed as follows: When an ulcer of the stomach is diagnosed, even if a copious hemorrhage from the stomach has just occurred, or, if in the absence of classic symptoms there is reason to believe that a patient has an ulcer of the stomach, then I first examine the blood, ascertaining the percentage of hemoglobin. The patient is then put to bed, the juice of five pounds of beef daily, properly prepared, is administered, until the percentage of hemoglobin becomes or approximates the normal, or nearly so, and then we prescribe a rest cure, as it is usually employed, lasting from four to six weeks, giving beef juice when necessary, always controlling the percentage of hemoglobin by regular examinations of the blood.

The general consensus of opinion as to the value of the rest cure is very favorable, and rightly so, but we must consider that by subjecting a patient who is already anemic to such a treatment, we do not meet all of the indications. By keeping the stomach quiet, we no doubt add to the chances which promote healing of the ulcer, while, on the other hand, by starving the patient, or by giving only milk and nutritive enemata, we make worse the anemic condition, thereby lessening the chances for healing of the ulcer. By administering the elements which are lacking in the blood, and putting the organ at rest, we meet both indications.

The immediate effect of the rest cure is, as a rule, very pleasing, but if we observe our cases critically after they have left "cured," we will find sufficient cause to correct our statistics, and the ultimate prognosis will appear in an entirely new light.

To outline my mode of treatment in a general way, I would recommend the following:

1. If we diagnose an ulcer of the stomach, or if, in the absence of convincing symptoms—which are so often lacking—we have cause to suspect an ulcer, we must at once ascertain the percentage of hemoglobin.

2. We advise the patient to go to bed, either in a hospital or at home, employing the services of a trained nurse.

3. We give the juice of five pounds of beef daily, as the case may require, to bring the percentage of hemoglobin up to normal as soon as possible. Prepared beef extract does not give the desired result. Peptonized beef solutions are not tolerated in sufficient quantity.

Leube-Rosenthal beef solution soon becomes objectionable to the patient.

Beef juice prepared as follows is generally well taken, and gives excellent results in uncomplicated chlorosis, and in secondary anemia, that is not caused by carcinoma, etc.

#### DIRECTIONS FOR PREPARING BEEF JUICE.

1. Order five pounds of finely-chopped round steak, to be brought at 8 o'clock every morning, or keep it in an ice-box from the day before. The fat should be removed before the beef is chopped.

2. Mix the meat with a teaspoonful of salt, and put it into the upper part of a double boiler. Cover without adding water.

3. Fill the lower part of the boiler with warm (not hot) water.

4. Keep the boiler on a kitchen stove for four hours, keeping the water in the lower part of the boiler just warm, so a hand can be placed on the latter without burning it. This will do, as a rule, but the use of the thermostat, regulating the temperature to 120 F., gives more uniform results.

5. Turn the beef every hour.

6. After four hours press out the juice with a potato-masher, spice, and let patient drink it in two portions, one-half at dinner and the other half at supper.

Five pounds of beef yield about a pint of juice, which will necessarily have to be taken in one portion at supper, if the patient works during the day.

In other cases, one-half should be taken at noon and the other half at supper. The juice should be of a roast-brown color.

After the percentage of hemoglobin has become normal, the patient should have nothing to eat or drink for from two to five or six days. During this time the teeth must be kept very clean, and a good mouth-wash must be used often.

Rectal-nourishing enemata may be given twice a day, preceded by a cleansing enema. Not more than one cleansing enema should be given before the food is injected. The nutritive enema may consist of one egg, five grains of pepsin, eight ounces of normal salt solution and a glass of claret mixed.

If the enemata should cause discomfort, they must be stopped immediately. I have observed serious collapse in a perfectly healthy man, 28 years of age, after such injection, and frequently discomfort was caused in others, quite out of proportion if we consider the slight benefit derived from such enemata. Nutritive enemata become really unnecessary when we allow our patients the use of large amounts of beef juice. After the days of total abstinence from eating and drinking, we give milk for a period of from four to six weeks, ordering beef juice whenever necessary. The patient is then permitted to partake of solid food, either according to Leube's diet, if all goes well, or, if I do not feel assured about the progress of the patient, Pentzold's diet is employed.

The immediate results of such treatment, if well applied to the individual case, are very gratifying indeed, but the prognosis of ulcer of the stomach is not nearly as good as our statistics would make it appear. A great part of the later complications occur, because:

1. Patients present themselves too late.

2. The diagnosis is frequently not made, because the so-called classic symptoms are not manifest.

3. Hemoglobinemia is not sufficiently considered, and, if so, not properly treated.

In conclusion, I wish to say that I am very much inclined to recommend gastro-enterostomy early, in cases of stenosis of the pylorus, particularly if I am convinced that it is caused by the scar of an ulcer of the stomach, on account of the frequency with which carcinoma originate from such ulcers, through mechanical irritation of their margins. Such a mechanical irritation is much relieved by gastro-enterostomy, and, therefore, the danger of carcinomatous development may often be averted.

Let me give the history of two cases, one to illustrate my mode of treatment and the second to show that carcinoma may develop from a very small ulcer of the stomach.

CASE 1.—Chronic round ulcer of the stomach. (Short extract from the history.)

October 22, 1900. Mr. B., aged 37 years; married, two children. Rheumatism and gout in the family. Measles, rheumatism twelve years ago, and ten or twelve times since laid up. Two or three weeks at the longest. Malaria.

Present trouble seems more indigestion, dyspepsia, bloating, sour; sometimes pains one hour, or four or five hours after meals. Pain feels as if someone had hold of his epigastrium, twisting him up. Burning pain, principally under sternum. Trouble commenced fourteen years ago, when he was traveling.

Lost from 178 pounds to 138 in a year, from 1886 to 1887. At that time more distress, no sharp pain, sometimes several weeks would go by without trouble. He feels it more during spring and fall. He never vomited. A week ago, on the 12th, he had a large hemorrhage, fainted at 2 or 3 p. m. on the closet; when he recovered there was vomiting, but apparently no blood. Had his lunch at 10:30, eating a little celery and drinking some hot Scotch whisky. At supper he had a very small oyster stew, and not half a slice of bread. At 7 a. m. took a hot water injection, and then passed a good deal of blood, most of which was dark. He fainted and came to, and after half an hour there was another small hemorrhage. Felt weak, but not excited. Urine: no albumin or sugar. Blood: specific gravity, 1049.

Diagnosis: *Ulcus ventriculi; dilatatio-ventriculi; gastritis chronica.*

The patient entered the hospital, and was put to bed on Oct. 22, 1900. He received the juice of five pounds of beef daily, given in three portions, and also some milk. On November 7, the specific gravity of his blood having reached 1060, he received nothing to eat or drink from November 7 at 6 p. m. to November 9 at 6 p. m., and after that milk, and off and on also beef juice. On November 23 clear soup and lentil soup, from which the lentils had been removed, was allowed. The first solid food was given on December 2, and gradually additions were made to the list of diet. He left the hospital on December 13, without having had any trouble with his stomach at any time, and his stomach has been well since.

CASE 2.—Adeno-carcinoma of the stomach originating from chronic round ulcer. (Case of Dr. G. Fuetterer.)

Mrs. G., 59 years of age, comes from a healthy family, but a brother died from carcinoma of the stomach, at the age of 42. About twenty-three years ago patient had dull pains in the epigastrium, which commenced with vomiting, that occurred daily, at irregular hours, for about three months. Every year similar attacks occurred, lasting from two to three months, the last one from June, 1899, to the time of her death, on Nov. 19, 1899. While she was under my care, she was treated for ulcer of the stomach in the hospital, after Leube's method. She improved very much, the pains disappearing almost entirely, and I expected her to get well. She was very anemic. After four weeks of treatment she left the hospital. Very soon, about a month after the patient had left the hospital, the pains recurred, the anemia grew worse, and emaciation became quite marked. As she had to be kept under the influence of morphin, and, believing that a carcinoma had developed from an ulcer, I recommended operation. On Nov. 16, 1899, an operation was performed, and a very small round ulcer, about the size of a dime, was found near the lesser curvature, somewhat to the left of the middle part of the stomach. From a portion of the margin of this ulcer had developed a whitish growth, appearing in the form of two nodules, measuring 1.5 to 1 centimeter. Macroscopic inspection and later microscopic examination showed that the ulcer had not healed, and that there was no tendency to healing. The small growth was an adeno-carcinoma, with infiltration of the submucosa, and muscularis. A gland which was attached to the outer side of the affected parts of the wall of the stomach affected was in a hemorrhagic condition, but metastases have, so far, not been found. Ulcer, growth and about an inch of the stomach's wall in circumference were resected, and this whole piece has been imbedded, cut and examined microscopically. We do not intend to describe the microscopic findings, as the microphotographs show them clearly.

*Conclusions.*—1. Although the patient's pains had disappeared almost entirely during the application of the rest cure, which led us to believe that the ulcer had healed, we found that it did not show the slightest tendency to heal, therefore the disappearing of the symptoms does not necessarily indicate that the ulcer has healed.

2. We have seen an adeno-carcinoma develop from a round ulcer of the stomach, which was very small, in-

deed, and this throws new light on the prognosis of chronic round ulcer of the stomach.

#### DISCUSSION ON PAPERS OF DRs. REED AND FUETTERER.

DR. JAMES B. HERRICK, Chicago, said that he was convinced that the importance of medical treatment in ulcer of the stomach had been underestimated by the medical profession, speaking generally. Besides the possibility of a fatal result by hemorrhage or peritonitis, with the occurrence of perforation, there are the more remote dangers of the appearance of carcinoma in the cicatrix, or contraction of the pylorus producing obstruction for which surgery offers the only means of relief. So that whatever contributed to our knowledge of the proper treatment of the ulcer of the stomach, is of great interest and importance. He had been acquainted with Dr. Fuetterer's studies of the pathology of ulcer of the stomach, and could say that his work deserved the highest praise. It seems that he had laid more emphasis, than upon any other cause, on the influence of the blood in the causation of gastric ulcer. He had pointed out the fact that, when the hemoglobin is deficient, we get a gastric ulcer and that until this deficiency is corrected, by proper treatment, the ulcers have no tendency to get well, and, in fact, resist all medical treatment. Yet pathologists tell us that they often find stellate cicatrices which they interpret as healed ulcers which have healed without medical aid. The line of treatment must take into consideration the nature of the causes which produced the ulcer, and the agency which keeps the ulcer from healing. This latter is mainly the constant motion of the stomach, after the partaking of food, the constant motion also in walking and in other movements of the body. Perhaps above all, it is kept from healing, by constant irritation from the gastric juice which is poured out during digestion. The method of treatment which seemed to be the most natural, would be that which allowed the greatest rest to the stomach. The experience of physicians generally would seem to indicate that the more nearly perfect rest for the stomach is secured, the more satisfactory is the result. This would involve placing the patient in bed, adopting the plan of Leube, keeping the patient at rest for a few days and giving him Carlsbad salts or alkalies, in order to overcome the acidity of the stomach, and using nutritive enemata. Very good results have been reported by this method; in fact Leube reported 70 per cent. of recoveries. The speaker's own plan is to carry out a modification of the method of Leube, namely, to put the patient at rest in bed, with absolute rectal feeding for three to twenty days, thus keeping the stomach walls at rest as perfectly as possible, and making the gastric juice small in quantity, so as not to irritate the stomach and cause spreading of the ulcer. This plan of treatment has been objected to as being unnecessarily severe, but he had never seen a patient who had objected to it and he had never found a rectum that refused the injections, when carefully given. He had never had occasion to regret its adoption. In old cases the results are not so satisfactory, but they are not satisfactory by any method of treatment. The point made by Dr. Fuetterer is of great importance: that we should not forget the condition of the blood. In the treatment just referred to, he had not overlooked the condition of the blood, although he had laid greater stress upon rest than he had upon the condition of the blood. Dr. Fuetterer lays more stress upon feeding than he does upon the rest cure. The speaker's reliance was upon rest in bed and upon milk. Before the patient gets out of bed, he is put upon the old-fashioned Bland's pill or some other form of iron. Under this plan of treatment, recovery is the rule. Dr. Shattuck of Boston, after reviewing all the various methods of treatment, came to the conclusion that this method of rest, with rectal feeding, gave the best results, and that the tendency to relapse was less by it than by any other. This tendency to relapse, which has been referred to by Dr. Fuetterer, is most discouraging, and in any system of treatment the liability to relapse is to be considered. The best method of treatment, if put into a few words, in all cases of uncomplicated ulcer of the stomach, is to stop all food from going into the stomach,

including water, then to put the patient to bed and feed him by the rectum for the first few days. After this, gradually give him food by the mouth and then give iron, and, only after a number of days when the patient has regained a good proportion of hemoglobin and of his strength, to allow him to eat ordinary food. He, like the essayist, advocated operative treatment in cicatricial obstruction of the pylorus. His own opinion was that early operation offers the best hope of relief. He also thought that early operation might prevent the occurrence of carcinoma.

**DR. G. FUETTERER**—The feeding is a very important part of the treatment. The plan he adopted is one that can be carried out by a trained nurse or any intelligent person of the household. He begins at 7 a. m. with an enema of a pint of warm water; if retained, it quenches thirst, and if not retained, acts as a cleansing douche. Then at 8, 12, 4, 8, and at midnight, he gives a nutritive enema, consisting of a dram of somatose, one egg, and a pint of milk, to which is added a pinch of salt. The patient is instructed to retain the enema and is assisted by the nurse. These injections are continued for 6, 10, or 15 days, or until the nausea and vomiting have all disappeared; then they can be cut down gradually, as feeding by the mouth is resumed. Occasionally an enema of warm water is given to relieve the thirst. For the relief of pain, he used, as Dr. Shattuck had recommended, small doses of morphin given hypodermically, which also accomplishes a good purpose in overcoming the annoying thirst, and quieting the movements of the stomach.

## GASTRIC HYPERESTHESIA AND ITS MANAGEMENT.\*

CHARLES G. STOCKTON, M.D.  
BUFFALO, N. Y.

The term gastric hyperesthesia has been applied to painful or distressing sensations arising in the functioning stomach, not so intense as gastralgia, but of enough severity to cause more or less discomfort to the patient. If we analyze the causes of these distressing sensations, it will be found that they depend upon various pathologic conditions. Unquestionably the term "hyperesthesia" is often improperly used. The truest use of the term is when it is applied to sensory states analogous to cutaneous hyperesthesia, so often seen in the neurotic. There is a comparatively large class of cases to which I have gradually come to apply this term. It is important that this class of cases should be distinctly understood, as the conspicuous sensory symptoms so much attract the attention of patients and physicians that there is often established a course of treatment for indigestion that really does not exist. The patients of whom I speak present symptoms that resemble those of hyperchlorhydria, and yet the conditions are not identical. Nevertheless the symptomatology is sufficiently alike to render it impossible to make a diagnosis without examining the gastric chemistry. There is commonly distress after eating, often occurring earlier than in hyperchlorhydria, also eructations of gas, and sometimes water-brash. There is often tenderness over the epigastrium, and a sensation of vague distress after meals that leads the patient to eat sparingly, hence there is loss of flesh and strength.

The examination of the stomach contents of these cases reveals the fact that the standard of hydrochloric acid is not above the normal; indeed, it is often below that seen in active individuals in good health, and still it is apparently the hydrochloric acid and the activity of the gastric digestion that causes the distress of the

patient. This is shown to be true by the relief of the patient attending the use of remedies that lessen the gastric acidity and slow the digestion, and similar, though less marked benefit, follows the selection of a diet of easily digested food. If these statements be critically examined it will be seen that the claim is virtually made that people without hyperchlorhydria have symptoms of that condition. This, in fact, is very nearly a correct statement of the case.

The systematic examination of the stomach contents of many cases during the past fifteen years has led me to the conclusion that there is no fixed standard of activity of gastric digestion and of the amount of free hydrochloric acid that is present in presumably healthy people. It depends for the most part upon the general strength and activity of an individual at a given time. It has long been known that the acidity of the gastric contents of the dog is so high that it would be unbearable in the stomach of man, and so, hardy workers in the north woods have gastric secretions that enable them to easily digest foods that are for most people indigestible—and this they do by means of a gastric secretion that is very active and highly acid. I have seen such individuals free from all stomach symptoms, with free hydrochloric acid ranging from .15 to .25, and a total acidity of over 100. Such gastric chemistry would prove to be very uncomfortable to the average student or brain worker. He is more comfortable with free hydrochloric acid not above .10, and this moderate strength of free hydrochloric acid and the proportionate lowered gastric activity will be found too active—the free hydrochloric acid in too great proportion for comfort—in the stomachs of delicate females whose nervous systems are hypersensitive, and whose organisms are not properly developed by outdoor life and physical exercise. Such people are often made comfortable by lowering the gastric acidity to a point indicated by .05, and occasionally we find patients showing manifestations of hyperesthesia who are uncomfortable so long as there is a trace of free acid in the stomach and whose symptoms can be relieved when free acid is present, by the administration of alkalies and antacids, and by diluting the stomach contents with fluids. On the other hand, if one, guided by the indications of gastric chemistry alone, regards these cases as instances of hypochlorhydria, and attempts relief by giving hydrochloric acid and drugs of a stimulating character, the symptoms are at once aggravated.

It has seemed to me that the question of hyperchlorhydria must not be looked at too definitely. It is arbitrary and unphysiological to make a standard and say that above this is hyperchlorhydria, and another standard and say that below that is hypochlorhydria, without introducing the personal factor of the patient. What is hyperchlorhydria in one person would be hypochlorhydria for another. It is possible in most cases of hyperesthesia to increase gradually the tolerance of the stomach for free hydrochloric acid and for a higher gastric activity in general, merely by improving the general health of the patient; that is to say, increasing his energy, his muscular and nervous activity. It is none the less necessary to resort to examinations of the stomach contents, and this should be done sufficiently often to make one familiar with the gastric secretion; then, by diet and treatment, the gastric activity should be kept at the highest point compatible with comfortable digestion, and yet within the limit of gastric tolerance. In this way can the stomach be developed, while the courage and resisting power of the patient are growing.

\*Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. Thomas Hunt Stucky, Leon L. Solomon and N. S. Davis, Jr.

In order to succeed in understanding these cases one must exclude inflammatory conditions, ulcer, erosions, food stagnation, and other conditions that might give rise to the symptoms. Gastropotosis can not be excluded, as that is a frequent cause of hyperesthesia. After having made the exclusions possible, it will be found that a large number of cases that present symptoms that closely resemble hyperchlorhydria can be explained by looking at them from the standpoint here taken, and managing their diet and drugs accordingly.

As a diet it is best to select, in the beginning, one that is very bland; for instance, milk or some milk preparation. To this should be added, first, the digestible farinaceous foods, then eggs; finally, meat juice at certain meals, and later scraped meat, meat powder, and next tender steak or chop, to which may be added some of the more easily digested vegetables. Thus, the diet may be gradually increased from step to step, always being careful not to go beyond the point of toleration. When found that the allowance has been too liberal (or in case it is found necessary even with a very restricted diet), and the stomach reacts unpleasantly, it is advisable in order to relieve symptoms to give after meals antacids as soon as evidences of irritation arise. Mixtures containing sodium bicarbonate, magnesium carbonate and the bismuth and strontium salts are commonly employed. The patient who may require these remedies regularly when busy as a school teacher, dressmaker, accountant or business man, may find that the digestion is comfortable without remedies, provided a vacation is taken, or a period of rest is arranged for after each meal. When the case is of long standing, it will be found that electricity is of signal service. The continuous current should be employed with gastric electrode, the negative pole in the stomach, and a current of from 5 to 10 milliamperes, of a low voltage, should be used two or three times a week for a period of five minutes. I have sometimes seen great benefit from the faradic current used in the same way. Unquestionably benefit may be had from hydrotherapy, but great care must be taken not to overdo the use of cold water. A very brief, cold spinal douche, the temperature carefully regulated, or the shower bath with the same qualifications, or the Scotch douche, are measures that can hardly be dispensed with when treating this condition as it occurs in the neurasthenic. When met with in the hysterical, great benefit follows the use of the *mistura asafetida* introduced per rectum, in doses of one ounce night and morning. It is necessary, however, to attend to the strength of the gastric chemistry while continuing the other measures.

It may be said that the cases to which I refer are not typical instances of gastric hyperesthesia. In reply I would say that it depends entirely upon one's conception of hyperesthesia. I have come to regard these as making up the largest class of patients to whom the term properly belongs. That the treatment is rational and suited to the condition seems apparent, for the reason that we have to deal with those in whom those distressing sensations develop in the stomach merely from the normal stimulus of food and digestion. Indeed, as has been stated, the symptoms arise when the stimulus is less than normal. It is, therefore, proper to regard these cases as instances of hyperesthesia. I am firmly convinced that there exists a misconception regarding the nature of many individuals thus affected, and that they are treated for diseases of digestion of which they are innocent.

In closing, I wish once more to insist upon the importance of the regular examinations of the stomach contents, in order that one may govern the diet intelligently.

There is such a thing possible as keeping a patient too long upon a very restricted diet, and the stomach instead of gaining in power, loses quite in the same way that the biceps atrophies for the want of use. And yet, if one is too ambitious and overtaxes the stomach in these hyperesthetic cases, there is produced in the patient real suffering, loss of courage and a disinclination to take sufficient food. I regard this as one of the most practical questions relating to the so-called dyspeptic. It is probably the most frequently met with of any of the gastric disturbances. It is a mistake to regard it as a disease of the stomach; it really is a derangement of the organism of which the stomach condition may be taken as an index.

#### DISCUSSION.

DR. W. W. TOMPKINS, Charleston, W. Va.—In these abnormal gastric conditions, we can not always diagnose between catarrh, ulcer, and carcinoma. He had in mind the case of a patient, who, eleven years ago, had stomach disorder and who was brought to a large medical center where a distinguished specialist had given a written opinion that the patient was suffering from cancer. The patient refused operation, returned home, and is living and well to-day. The speaker had been uncertain in his diagnosis at the time, but had come to the conclusion since then that it was a case of gastric ulcer and not cancer. The diagnosis on the basis of probability would be gastric ulcer in a young female; in persons who are gluttonous at the table, it would be gastric catarrh; but in advanced middle age, it would be gastric cancer. In many cases the diagnosis is uncertain and we are in the dark. One speaker referred to cases cured in two or three weeks; his own experience, however, was that these patients do not get well in a few weeks. He wished to put himself on record as opposed to putting these patients in the hands of the surgeon. He considered it a crime to operate in all cases and the physician who sends his patients to a surgeon for operation is *particeps criminis*. He tried to keep his patients from thinking of an operation. Many cases do not need it and are better without it. The essayist spoke against prepared foods and explains a rather troublesome process to get the beef juice; but the speaker could see no objection to using a good article of commercial beef juice. With regard to the medicinal treatment, iron had been mentioned, but he preferred arsenic in the form of Fowler's solution. He also used deodorized tincture of opium in small doses with advantage.

DR. C. JONSSON, Clinton, Iowa, found it often almost impossible to differentiate between ulcer and carcinoma or neurosis of the stomach, but any of those conditions were accompanied by pain and he considers the pain as an important factor in producing malnutrition of the body in general and deficiency of hemoglobin. He finds it necessary to use an anodyne such as codein, hyoscyamus, or cannabis indica in sufficient doses to relieve the pain. The nutrition of the body will improve as a consequence and the treatment will often produce a cure.

DR. HEINRICH STERN, New York City—The administration of hydrochloric acid for the amelioration of hypochlorhydria and kindred anomalies depending to their greatest extent upon systemic malnutrition, although universally recommended, is certainly an irrational proceeding. The moment the clinician becomes better acquainted with the production of gastric hydrochloric acid, he will cease to prescribe it for gastric insufficiencies and disorders. Hydrochloric acid is by no means a product of the peptic glands as generally supposed. The hydrogen or the chlorin of the hydrochloric acid of the gastric juice must certainly be derived from the blood. The acid as such does not occur in the blood nor in the lymph. The component elements must therefore combine somewhere in the peptic glands. We find in the blood free hydrogen-ions; however, they occur in small quantities only. If the nutriment is absolutely devoid of chlorin, and if the saliva is as much as possible prevented from admixing with the food and from entering into the stomach, no hydrochloric acid can be produced in the peptic glands. This fact convinces that it is the hydro-

gen-ion of the hydrochloric acid which must be derived from the blood. The place where the hydrogen-ions combine with the chlorin-ions to form hydrochloric acid can not be the gland-cell, but must be the glandular wall. The latter is a semi-permeable membrane, which prevents passage of the free chlorin-ions, but permits on the other hand the migration of the hydrogen-ions through the membrane. The production of hydrochloric acid can not ensue without a certain stimulus. The latter is supplied by the presence of free chlorin-ions on the inner surface of the stomach wall. The administration of hydrochloric acid, it is true, may furnish such a stimulus; however, for this purpose, it is at present not prescribed at all.

DR. MARY MCCOY, Duluth—The physicians as a rule pay too little attention to the preparation of the food of patients. It is a matter of vast importance to every physician. If chlorotic patients come for treatment, you can take it for granted that if they are allowed to take improper food and indulge in every wish they will have gastric ulcer. It is therefore of very great importance that physicians should be competent to direct the proper food and its proper preparation. Let us, for illustration, take up the common advice to a patient to use cereals as an article of diet. Most patients only boil a cereal, like oatmeal, for twenty minutes, when it should be cooked at least five hours. There is too much of a tendency on the part of physicians to rely upon the patients or their friends to prepare proper articles of food. Every physician should make a special study of dietetics. The combination of food also has much to do with the causation of gastric ulcer and other stomach disorders.

DR. THOMAS MCCRAE, Baltimore—In the clinic of Dr. Osler a series of cases of gastric disorder had been studied which were of interest in relation to the papers that had just been read. It was found that the diminution of hydrochloric acid in the secretion of the stomach, to almost, or entire anacidity, not only simulated gastric hyperesthesia, but also hyperchlorhydria. Experience had shown that the administration of hydrochloric acid was not helpful, but frequently detrimental, in these cases. The question of diet is a very important one. Treatment by drugs is often not of much use. Pain and increased sensitiveness, however, should be relieved. He recommended the following formula in gastric hyperesthesia: Acid carbolic and tinctura iodi  $\text{āā}$  m. i, glycerini 3ss; to be taken when required, to relieve pain.

DR. DORA GREENE WILSON, Kansas City—In her experience with gastric ulcer, she had found that there were many cases associated with a catarrhal condition of the stomach. In such cases she had found much benefit from hydrochloric acid given in broken doses, five minims of the dilute acid to be given after each meal, and then five drops more half an hour later. This prevents fermentation and aids digestion. The results are very satisfactory when given in this way.

DR. BOARDMAN REED, Philadelphia—He was much pleased with the confirmation that Dr. Fuetterer had given from his experience of the ill effects of hydrochloric acid when given indiscriminately. There had been no lesson impressed upon him more strongly, by his clinical work, than that great harm can be done by this acid, when its administration is not based upon examination of the stomach contents, especially with persons having a normal amount of it in their gastric juice, and still more with those having an excess. Many cases of gastric disorder have been caused by HCl when prescribed without an examination of the stomach contents. It would be well if the term dyspepsia were to be abolished from our language; it means only "difficult digestion" or distress after eating, and is applied to a number of diseases, requiring widely different treatments. Some of the speakers have said that they did not see how HCl could cause increase of acid secretion from the gastric glands. A little experience with the burette would soon convince them. In cases of deficient secretion the administration of small doses will increase the activity of the glands. In cases of normal secretion, or of excessive secretion, it does much harm by causing irritation. He expressed admiration at the result reported by Dr. Fuetterer. The important observation that he had made as to the role which anemia exerts in the

production of gastric ulcer, is novel and deserves attention, and the good effect of beef-juice in bringing about improvement is notable. In conjunction with rest in bed, it is of great value. Gastric hyperesthesia is a very important symptom in gastric disorders and calls for more attention than is ordinarily given to it. We can not lay too much stress upon the amount of hydrochloric acid present in the gastric secretion, in cases of gastric hyperesthesia. Some have an increased while others have a reduced percentage of it and the hyperesthesia is greatly increased by the administration of hydrochloric acid in the former class of cases.

DR. G. FUETTERER, Chicago, approved of the remarks of Dr. Herrick as to the value of rest in combination with the diet. In reply to Dr. Tompkins' statement about commercial meat juice, he said that his objection was that if given in equal quantities the expense would be too great; that it is not as reliable as the fresh preparation and that the comparative results do not give such an increase of hemoglobin as he had obtained from beef juice. As regards surgical interference in narrowing of the pyloric orifice from ulcer, it is no crime, and it is not criminal, to recommend gastro-pylorectomy in some cases of gastric ulcer, but on the contrary, the only humane method of relieving the patient and preventing death by starvation and the development of a carcinoma. The object in giving the beef juice is to increase the hemoglobin, since according to the views expressed in the paper the ulcer is caused by the lack of hemoglobin, and heals when the hemoglobin becomes normal. The suggestion as to the use of morphin is a very valuable one. As regards giving rest to the stomach, it is a question whether or not you do give rest to the stomach by stopping the food. The empty stomach may move as much as the stomach containing food. By giving morphin we can quiet the motion of the stomach as well as relieve the pain, and favor cicatrization.

With regard to Dr. Reed's paper the author had called attention to a very important point and that is that pepsin and hydrochloric acid should not be given indiscriminately, as they often are. He had also made another very important statement, which was that the administration of hydrochloric acid in achlorhydria not only has a transitory effect, but, in the course of time, it really brings about the restoration of the normal proportion of hydrochloric acid in the gastric secretion, which is of the highest importance. Dr. Osborne said it was a common mistake to treat cases of gastric hyperesthesia by restricting the diet, as if they were cases of dyspepsia, when they are not. Referring to Dr. Reed's paper he said that he could not understand how the administration of an acid could bring about an increase of an acid secretion. He thought the hydrochloric acid was useful in improving the general nutrition, and thus enabled the stomach to better perform its work.

DR. C. C. STOCKTON—In regard to Dr. Reed's paper, explain the fact how you may, there is a decided advantage in administering hydrochloric acid in cases where the acid is deficient. As regards Dr. Osborne's statement that the administration of the acid would not stimulate the gastric glands, so much as an alkali given before meals, he had tried the latter many times. While the observation may be true in animals, it was not true in his clinical experience, basing his remarks upon chemical tests and clinical cases; he withdraws the tube as early as possible, so that the presence of the tube will not increase the hydrochloric acid, and he found that the result was negative and that the alkali did not increase the acid secretion. The improvement of digestion after giving the HCl may be in part due to the effect upon the entire organism. He did not think that the mere administration of small doses of HCl would increase the gastric secretion, but its administration would give the stomach increased power to act. In regard to operative measures, he wanted to confirm the statement that it is wrong to allow a patient with decided obstruction from stricture at the pylorus to go without the relief to be obtained from operation. The statement with regard to morphin, that it is likely to lead to the formation of a habit, is a just criticism. He thought that hunger could be overcome by the use of cocaine, which, if properly used, would accomplish the same purpose with less harm. The fact remains that small doses of ano-

dynes abolish stomach movement and pain. He had been much pleased by the remarks made by Dr. McCoy who said that the physician should devote more attention to the preparation of food. He had no doubt that many of the gastric conditions that we are called upon to treat are caused by abominable cooking. Even in the preparation of bread, we see a great many failures in the homes of our patients. It is surprising that our mortality is not greater when we reflect upon the unintelligent preparation of food all around us. As to the remark of Dr. McCrae, he would state that his own experience with gastric hyperesthesia was that pain and hyperesthesia have accompanied deficient secretion of HCl; the pain is not always increased by taking food, it comes on paroxysmally and is a distinct neurosis. Although it is accompanied by this disturbance or absence of secretion, he believed that the most intractable cases of gastralgia are those in which the gastric secretion is perfectly *nil*; but these cases are not due to atrophy of the gastric tubules, because he had seen some in which the secretions were afterwards restored. Another speaker referred to the use of hydrochloric acid after taking food in order to prevent fermentation. It is a common mistake to attribute the symptoms of pain or distress to fermentation in the stomach. Most of the prescriptions for indigestion are based upon the idea that the disorder is caused by fermentation; but his own observation had lead him to conclude that it was due to disturbed innervation, or motility, and resulting disturbance of secretion. Most of these cases are based upon some disturbance of the nervous system, and they may be treated with hydrochloric acid without benefit until that condition is removed. Distension of the stomach that is complained of, is more often a sensation of distension rather than actual distension. He asked that in cases of supposed fermentation an examination of the stomach contents be made to find out if organic acids are present or not.

## STATE SUPERVISION OF MARRIAGE.\*

W. H. HEATH, M.D.

OF THE DEPARTMENT OF HEALTH.

BUFFALO, N. Y.

No time need be occupied before this audience in demonstrating that marriage is the foundation and keystone of family and state integrity, or that it is the most fundamental institution of society. Nor that the family is the natural and historic basis of it, being the origin of order, law, morality, education and justice.

Neither need time be taken to show that indiscriminate union is associated with the gravest consequences, the influence of which, either directly or indirectly, is associated with the most gigantic evils, in fact with almost every offense against society and the state. It loosens the family ties, tends to immorality, and diminishes mutual and parental responsibility.

From data in the premises, exact knowledge, we are in a position now to assign to heredity its proper importance, and to coincidentally formulate some plan or procedure having for its object such practical supervision of the whole question as will minimize and ultimately eradicate the possibility of evil influence through it. There can be no question of the right as to the necessity of the state to exercise its jurisdiction in this field as in others affecting the public welfare. To preserve itself it must be strong, and its strength depends upon its future citizens and their characteristics. Heredity, the imprint of sexual union upon its product, is one of nature's fundamental, universal, immutable laws. As you breed, so shall you reap; or beget. How important, therefore, and really how imperative is it that there be

scrutiny and supervision, or attention given in some way over those who propose to send forth others into the world; this must be done to prevent not only the individual degenerate, but to protect society and the state from his possibilities.

As a matter of fact, the state, to a limited degree, already asserts this right and authority, though chiefly as to certain degrees of consanguinity, by no means the most important feature. It should go further and extend this to moral, economic and other factors, with established or proven unfavorable possibilities. The state having this right in the premises, it would appear that now is the auspicious time to inaugurate a change. Never before were the people more in the spirit of advance. The influence of the great discoveries and innovations in commerce, art and science have been educational in no small degree, and have prepared the public for many changes which an era ago would not have been considered. The struggle for life is growing keener, survival of the fittest more and more in evidence, the standard in everything made higher, and coincidentally with and as a result of this there is an enormous augmentation of the submerged mass. Any change, therefore, that would diminish the number bound to sink, the number who by endowment can not cope with life that confronts them to-day and that will improve with environment, is indicated. It can not, therefore, be doubted that supervision to any degree that will make the masses stronger where weak, better where in fault, will, as soon as demonstrated, command the attention it deserves.

The problem, however, is one of the greatest difficulty, dealing as it does with a custom or procedure as old as man himself. Into the problem enter both sexes, under complex conditions, prompted by the greatest emotions and the strongest passions, and that, too, at a time of life when these factors are at their highest and when reason and judgment are yet unripe.

As a step toward reform it is proposed that no marriage be performed, be legal, or the offspring thereof be legal, if the marriage be performed without license; that marriage by license be mandatory by law upon all persons entering into the matter, the contracting parties, the officiating person and the witnesses. This license should be issued by the proper authority or official, only after certain conditions have been complied with and certain data furnished (analogous in some ways to the procedure adopted in issuing a burial permit in properly organized health departments). Such license should be issued upon certain data, contained in three certificates, viz:

A. *Certificate of Health and Heredity.*—This should be furnished by the family physician, or in the absence of such, by any reputable physician. It should contain certain data covering the family history, such as: 1, age and cause of death of immediately preceding ancestors; 2, the existence of predisposition to insanity, tuberculosis, cancer or other transmissible diseases; 3, of any preceding illness bearing upon present or future health.

B. *Certificate, Either Special, Qualifying or Educational.*—This certificate should be issued upon, and represent attendance—with or without final examination—upon a short, practical common-sense course of free lectures; these to be given preferably at night, delivered under the auspices of the municipality, town or village, at some convenient place such as the high school, academy, court room, church lecture room, etc., by a suitably qualified person—matron for the females, master for males. These courses should be adapted to each sex, and

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Hygiene and Sanitary Science, and approved for publication by the Executive Committee of the Section.

should include in a general way didactic instruction, and when indicated and practicable, should be supplemented by demonstrations in the following subjects: 1, outlines of physiology of infancy, childhood, puberty; 2, function of sex, sexual life, its care and abuse; masturbation, menstruation, childbirth, reproduction, growth and development; 3, personal hygiene, physical and mental development; 4, venereal disease, and those due to violation of sexual laws; 5, domestic and household economy, domestic hygiene and sanitation; 6, alcoholism and tobacco, and 7, morality and the moral sense. The scope could be determined by a committee of educators, composed say, of a school principal, a medical man, a lawyer, or some prominent citizen. These lectures should be modified, greater emphasis being given to that which relates respectively to each sex, and include additionally such other pertinent matter as will be conducive to good citizenship, enlightenment in civic affairs, and a high moral standard.

*C. Certificate of Ability.*—1, Evidence of capability of support, that the parties themselves and their offspring will not be a care upon the community; 2, evidence that the individual is not an habitual criminal, when such evidence seems to be indicated.

A change in the mode of procedure of such a momentous matter as marriage must of necessity, in the present state of affairs, be gradual. Real knowledge in the premises is limited to the thinking classes. Public opinion is unformed, and therefore legislative action toward this end is impracticable.

To demonstrate the feasibility and beneficial results of state supervision upon some such lines as indicated, and create public sentiment, *some inducement should be made* for those contemplating marriage to comply with the conditions and to inaugurate such a system. As an inducement certain civic advantages might be offered:

1. To contracting parties themselves.—To male contracting party there might be given, *a*, limited state military service; *b*, limited jury service; *c*, a certain number of advantageous counts in civil service examinations for public services, the fire and police departments, clerical positions, etc.

To female contracting parties there might be given, *a*, a certain number of advantageous counts in civil service examinations for the public services, as in schools, hospitals or other municipal work; *b*, privilege to vote for school boards and other minor officers.

To both the right might be given that if overtaken by adversity increased assistance from the poor department will be given them.

2. To their children.—The offspring of such unions, as a result of selective breeding, may be assumed to be capable of greater development and possibilities, and therefore of greater value to the state. To these some preferment might be accorded, much in the same lines, such as, *a*, state military exemption, or preference in promotion in that; *b*, civil service counts and preferment in police and fire departments, clerical positions; *c*, certain free scholarships when practicable.

It is proposed that for the present this special license be voluntary, because under those conditions it appeals to the individual. It need not influence the marriage of others who for reasons of their own do not desire to avail themselves of its benefits; for those the ordinary license system can be used.

The benefits to be accrued from this special license system, if carried out, are not difficult to appreciate. These especially appeal to the writer: It would throw

out safeguards around the young and indiscreet, and protect womanhood against designing men; dignify and elevate the marriage ceremony; deter the vicious; educate all classes to the fact that it is a serious step and not to be undertaken lightly; enhance the status of marriage and the married state; diminish divorce; insure a higher type of progeny; diminish hereditary disease; abolish predisposition to many other diseases; improve the public health and diminish mortality; increase morality; strengthen the state, and finally, pave the way to precede some other needed reforms of a similar nature.

Objections there will be. There are to every innovation, and this will be no exception. Prominent will be the objection that it interferes with a matter ordinarily guided by instinct and sentiment, and materializes it. Then again, the difficulty of enforcing it will be brought forward. The latter is a valid objection. There would be great difficulty, but not if the system were approached gradually and if it extended throughout all the states. Another possible objection is that any qualification to marriage will be conducive to immorality. My answer is that it be by special license, optional not mandatory.

Those who prefer can be married under ordinary license. It may also be objected that statements would be falsified. To that it can be answered that all statements should be under oath, with penalty, and that the special license be optional. Further, that publicity to private matters might be a consequence. That, however, would not be true were the licensing official under court orders and the records not public. Information to the family physician is privileged communication by law.

Aside from these radical, far-reaching reforms it would greatly strengthen the moral framework if there were a revision of marriage laws, to the effect that the limit of age be increased; that the ceremony always take place in the presence of witnesses; that it be given publicly; that marriage between intoxicated persons be forbidden, and that it be invalid if the ceremony be performed after 10 p. m.

While it may not be expedient to attempt legislative action at once, it does seem clearly in the province of this great association to discuss and to agitate the question in all its bearings. It should present it to the public in a rational, scientific, practical, everyday manner, clarifying it of ambiguity and showing its great value and significance.

#### DISCUSSION.

DR. SENECA EGBERT, Philadelphia—It seems to me that we are not ready for such an innovation as this would mean, for the reason that the great mass of the public is not educated to it and that must come first. My experience, as a physician, as well as a teacher of hygiene, in the last twelve years has been that the great majority of humanity, even in our centers of population like the great cities, are virtually ignorant of the matters to which this subject pertains, and that it is largely through the lack of education, through the unwillingness of parents to instruct offspring and through the lack of opportunities for education in this matter that things are as they are. Now, it seems to me that to offer such a proposition as this paper suggests and to give it state authority or state sanction without a very considerable preliminary education in regard to these matters relating to sex and marriage, would be to create so much opposition that it would wreck it in the very beginning and retard the movement. The idea is unquestionably all right, theoretically, but the opposition that would arise among the public in general, it seems to me, would be so great that it would throw the movement back and prevent its development rather than help it, and for that reason I feel that we in this country—at least I know a part of the country

—are not ready for it. If I am not mistaken, there has been a proposition in this very state; a law has been offered in the Minnesota legislature to require a physical examination or a physician's certificate as a preliminary to all marriages. I do feel that I know of no locality in the country where the general education of the people and their general knowledge is not such that a measure of this kind would develop a serious opposition to rather than a general and sustaining acceptance of its requirements.

Some of the suggestions made in the paper were to my mind excellent. It seems to me that there could be no better thing offered to the public at large than these lectures, for instance, that the Doctor mentioned and suggested; but we must remember that to give a course of lectures as suggested would require a very large amount of time, say a course running through an entire winter, and though I doubt whether one series of lectures would be sufficient in which to give the public such information as they ought to receive, my experience has been that the ordinary laity are not willing to attend any series of lectures that necessitates more than six or eight different meetings. However, there is no doubt that such education would be excellent. Again, while I believe that some of the people are anxious for education in these matters, I doubt whether we will secure it best by giving lectures with state or municipal sanction. I think it will go better and quicker through private sources, and when I say private sources, I mean sources distinct from the state or the municipalities, for instance. There is a feeling that the state should not go too far in interference with the rights of an individual. Many of us have a feeling that no state and no society has a right to contravene certain of our rights. Therefore, it seems to me that for any state to establish rules to regulate this matter at the present time will lead to a worse condition of affairs than there is at present. It would lead to a disastrous condition of affairs, because people who felt that their individual rights were transgressed upon and who were not willing to follow out the requirements of such state enactments would be induced to oppose them, and there would be a worse condition of affairs than there is at the present time. There is not a particle of question about the advisability of selected marriages, but we have a great many million people in this country and, for a long time to come the marriage will be a matter of simple emotion or notion, and so I think we will have to put up with the present dangers and risks and evils until we can build up from the bottom with that education which is going to be the primary motive power that will bring about in the future such action as is outlined in this excellent paper. If it only comes soon I shall be glad.

DR. L. H. MONTGOMERY, Chicago—While we are all individually at least in favor of the steps advanced by the author, it would come under the head of being called unconstitutional. There is a good deal to be said in favor of it, but there are a few objections to it. As sanitarians, the theory sounds very plausible and the most desirable thing in every respect, but to obtain such practical results it does not seem that this is to be in the very immediate future.

DR. L. B. TUCKERMAN, Cleveland—The beauty about all these schemes for regulating the question of marriage by education of the character spoken of is that they appeal to those to whom no appeal is necessary, and, to those to whom they ought to appeal, considerations of this kind do not appeal in any way whatever, nor can they be made to appeal. The thoughtful men and women of the industrial classes are already limiting marriage to a very great extent. Hon. Carroll D. Wright has collected some statistics recently of over 17,000 of men of influence locally among the trades unions in some twenty-two cities, and out of that 17,000 there were 15,000 and over unmarried—7 out of 8. Very evidently those 15,000 did not need any caution on the question of marriage. They were the more thoughtful among their associates and the simple fact of the uncertainty of their employment, the question of whether their job of \$1.50 a day would hold during their married life, made them abstain from marriage, and there is enough regulation of that kind among those who think. Those classes of industrial workers are not marrying to any great extent. That

relegates the marriage question among the masses of the population to those who do not do any thinking, but simply follow a physical impulse and for those who do not do any thinking, what use is there of undertaking such educational work!

DR. F. C. VALENTINE, New York City—The state has no right to infringe upon the inborn privileges of individuals. Is it an inborn privilege of mine to take an axe and drive you all out of this room? Not at all. Yet, the possessor of a residual gonorrhea may kill the woman he marries and may cause the state to be loaded with charges, children gone blind from the gonorrhea which was transferred to an innocent woman. Of syphilis I need not speak. Eloquent men have discussed that matter thousands of years ago when they promised that the sins of the fathers would descend to the third and fourth generation. We can not, it is quite true, as long as our present, perhaps theoretically the best, form of government exists, limit the rights of the individual, and especially in this one regard. But as long as we can quarantine cholera or small-pox or scarlet fever so well, I think the state is entitled to quarantine the two diseases that kill more than all others put together. In August of last year, Neisser of Breslau, at the Congress for Venereal Diseases in Brussels, showed that gonorrhea was a disease second in frequency only to the measles. He showed it from carefully made statistics, and yet in this country we make no effort to protect the public from the devastation of this one disease. It is quite true that the committee which last year here reported on the subject of marriage of gonorrheics were practically ruled off the floor because venereal ailments are not reportable diseases. But there can be enacted laws, through your influence, which will make marriage impossible without a certificate from a qualified physician that the would-be husband is free from gonorrhea and syphilis. You say that is a very difficult and complicated task? I agree with you, until we are educated in the matter. But is it not far more difficult and complicated for the state to support blind paupers, grown blind in consequence of gonorrhea? Is it not a fact that 80 per cent. of the children born with eyesight and who went blind within forty-eight hours after their birth, lost their sight on account of gonorrhea? Is it not true that 80 per cent. of the women who died of diseases of the reproductive organs, died from gonorrhea acquired innocently from their husbands, who imagined that they were cured? Now, I do not think that all men are selfish, but I do consider ourselves the weaker sex, because no woman, I think, would intentionally marry if she could communicate any disease. Men do it through ignorance and through weakness. I therefore think it behooves this Association, and particularly this Section, to make known to the legislatures the really easy manner in which one who has suffered from gonorrhea can be examined to decide whether he is free from the disease. This subject is entirely too wide a one for any five minutes' discussion. As you well know, however, it may be treated. There are other men who will continually bring up this subject before the Section, until eventually something is done about it.

## INJURIES OF THE CHOROID, WITH REPORT OF CASE.\*

ELLET ORRIN SISSON, M.D.  
KEOKUK, IOWA.

Injuries of choroid *per se*, with the exception of rupture, are so rarely seen, in fact it is so nearly impossible for them to take place without involvement of other ocular structures, that they can simply be alluded to as a possible occurrence. Small foreign bodies may pierce the sclerotic or the cornea and lens, and lodge in the choroid, and can often be detected there with the ophthalmoscope, and incised wounds of the sclerotic very frequently involve the choroid to a greater or less extent.

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Wüldemann.

Hemorrhage into the choroid and retina may produce extensive changes in these membranes and impair the sight materially if the macular region is affected. Oliver<sup>1</sup> reports an interesting case where a boy was struck in the eye with a stone. Shortly after the injury both choroidal and retinal hemorrhages were detected. Later pigmentary and atrophic changes took place and vision was reduced to 20/40.

The most common injury, as previously stated, is rupture, the result of a contusion or a direct compression of the eyeball as a consequence of a shock, that has been imparted to the orbital or the peri-orbital bones by a blunt body, and this is very often complicated by a rupture of the external layer of the retina. In the great majority of such cases this solution of continuity of the choroidal tissues is usually single and is situated between the optic disc and macula lutea, very rarely to the nasal side. Cases of double, triple and even quadruple rupture have been seen and reported by Teillair, Fage and others.

The case that I have to report, while in the main similar to the majority, presents some peculiarities. In the first place, the rupture, which was an extensive one, was

(Rupture of the Choroid (Sisson).)

to the nasal side of the papilla; secondly, the case was complicated by a spinal lesion in the lumbar region, which was said to have existed since the patient was 3 years of age. The visual disturbances were very great. The case was taken into the courts, and the questions that had to be considered were: Was the blindness the result of the injury to the choroid or the spinal lesion? Was the patient a malingerer?

T. D., age 16; May 15, 1897. Patient received a blow on the right eye from a rock thrown by a motomeer. When called, found an extensive cut in the soft tissues, covering the superciliary ridge; great swelling and ecchymosis of the lids. A further examination revealed the presence of a foreign body in the cornea, which upon removal proved to be a small piece of stone. Instilled atropin, prescribed an antiseptic wash and ordered patient put to bed. He made an uneventful recovery.

On Oct. 4, 1897, patient presented himself at my office for examination, saying that since the injury he had been almost totally blind in the eye. In the meantime he had sued the company for a large sum of money. At this time the following history was obtained. When 3 years of age, patient fell and broke his back, and has had to walk with a crutch ever since. An examination revealed the following: There was a visible angular deformity in the lumbar region of the spine, motor paralysis of the left leg and both patellar reflexes were absent.

He did not remember of ever having suffered any pain at any time. An examination of the eye showed the following conditions: V. of R. E., 2.5/200; V. of L. E., 20/15. Field of vision in R. E. was very much contracted. Pupil was of medium size, responding only to strong artificial light. A small rent existed in the lower part of the circumference of the iris. Only a very slight opacity was seen on the cornea at the spot where the foreign body had lodged. The ophthalmoscope revealed the following: To the nasal side of the optic papilla, about three papilla-diameters, and extending in a curved direction, the concavity directed towards the papilla, there was a rupture of the choroid, about four papilla-diameters in length, at the upper and lower extremities, and on either side of the rupture there were large deposits of pigment. The central part of the rupture was perfectly white, and the blood vessels could not be traced over it, showing that there had also been a rupture of the retina. The nerve head was grayish. Ophthalmoscopic appearance of left eye was normal. The usual tests showed that the patient was not a malingerer.

December 11, 1897, condition same. Patient complained of pains in the head at intervals.

January 13, 1900, V. R. E., fingers at 6 inches; L. E., 20/15. Palpebral and bulbar conjunctiva both eyes slightly injected. T was — in both eyes. Ophthalmoscopic appearance of right eye, same.

January 16, 1900, patient came to office complaining of the right side of the face paining and burning him, which he said had not existed previous to the injury. Condition of the eyes same. This was the last time patient presented himself.

These are the variety of cases that are most puzzling and upon the medical expert's opinion may hang the decision. As to just what influence, if any, was exerted by the spinal lesion is a question. We are told that in those much rarer cases of organic injury to the spinal cord, or of myelitis, or of hemorrhage in, or inflammation of its membranes, following on railway and other accidents, organic eye disease seldom results. As regards optic neuritis and optic atrophy, which used to be held as frequent consequences of spinal injuries, Thorburn<sup>2</sup> states that the slight spinal injuries are very common, but there is no evidence that they tend to be followed by changes in the optic disc. Such injuries are, however, in rare cases followed by chronic meningitis and myelitis, and in the latter condition there is *a priori* probability or possibility that optic neuritis may supervene.

Page<sup>3</sup> says there is no evidence of pathological change in the optic nerves being common in cases of spinal injury and nervous shock. Albutt<sup>4</sup> found hyperemia of the optic papilla with some indistinctness of its margins and overfilling of the retinal vessels, but no optic atrophy, nor tendency of the condition to pass into optic atrophy, and referred the changes he found to secondary, sub-acute meningitis at the base of the brain. It is now well-nigh a quarter of a century since Albutt published these views, and little or no confirmation of them has since appeared; yet even Albutt did not see optic atrophy as the result of spinal injury. In the case reported it is hardly possible that the loss of vision was the result of pre-existing spinal lesion.

The author presents this clinical picture for what it is worth, fully realizing, as stated in the outset, that the injury itself presented no very striking peculiarities, but the complications and the medicolegal aspect of the case make it of interest to the practicing specialist.

# A NEW COMBINED ELECTRO-CAUTERY INCISOR FOR THE BOTTINI OPERATION FOR PROSTATIC OBSTRUCTION.

HUGH H. YOUNG, M.D.

Head of the Department of Genito-Urinary Surgery, Johns Hopkins Hospital Dispensary.  
BALTIMORE, MD.

Although the electro-cautery operation was brought out by Bottini as far back as 1876, it was not generally adopted until 1897, when Freudenberg presented to the profession a greatly improved instrument, and followed it up by numerous convincing articles. During the past four years this operation has been performed very extensively, and we are now in a position to stop a moment, look over our results, and discuss the shortcomings of the operation, as well as its merits.

Freudenberg's large collection of operated cases probably shows very accurately the value of the procedure. The statistics are as follows: 752 cases, in which the result was good in 86½ per cent., a failure in 7½ per cent., and the mortality between 4 and 6 per cent.

These figures, if correct, undoubtedly show much better results than can be claimed for any other operative procedure. Castration, while peculiarly effective in a certain class of cases, has been woefully unsatisfactory as a routine procedure, and has justly been relegated to the list of operations historically interesting, but practically valueless.

Prostatectomy thoroughly performed is undoubtedly an operation of great value. There is no question that the statistics as to the value of this operation are entirely misleading, for many reasons; principally because in most of the recorded cases (and in all until recently) the operation was entirely inadequate—merely a nipping off of the most evident intravesical projections, leaving the equally important parts of compression in the deep urethra untouched. There is no question, however, that a thorough removal of the entire gland, which can generally be easily accomplished by enucleation with the finger, is a very successful operation, and entirely satisfactory when perfectly accomplished.

There are, however, several varieties of prostate which are unsuitable for this operation, principally the small and the sclerotic varieties. This, however, is not the principal objection, but the fact that in the majority of instances we are confronted with patients too old and too feeble to safely undergo the shock of a satisfactory prostatectomy. It is for just this class of cases that the Bottini operation has proved such a blessing, and has achieved really wonderful results. On account of the success of the cautery operations in the otherwise hopeless cases, it has become more and more the question whether it should not become the method of choice in all manner of cases. Since there are, however, a certain number of failures (10 per cent. or more) and a certain mortality (between 5 and 8 per cent.) shown by the Bottini operation, it still remains questionable whether it should replace prostatectomy, especially in younger patients. To settle this point more extended investigation is necessary. It also behooves us to study the causes of failure and fatality in the Bottini operation, with a view of finding means of obviating both as far as possible.

Among the causes of death besides uremia, shock, sepsis, etc. (presumably unavoidable), we find recorded several not unavoidable reasons, principally from improperly placed or too lengthy incisions. In the first

category are deaths from the cautery blade burning its way into the rectum, due, as has been shown by Freudenberg, to the fact that the beak of the instrument became caught in a postretrectal pouch, which is separated by only a short space from the rectum. In the same class are those fatal cases in which the entirely useless anterior cut was made and penetrated (as might have been expected) into the space of Retzius. In the second category are a number of cases in which the operator has rashly made his incisions too long, resulting in the rupture of the urethra in front of the prostate, and sometimes fatal hemorrhage from division of perineal vessels.

The statement of certain writers that incisions of 4.5, 5 or 6 cm. in length were often necessary to remove the obstruction is absolutely without pathological substantiation, and undoubtedly liable to lead to a great many serious blunders in the profession. Very rarely, even in the very largest hypertrophies, should an incision over 3.5 or 4 cm. be made, first because it is unnecessary, and secondly because it is dangerous. Deaths from any of the causes outlined above are preventable, and should in the future be eliminated from the statistics.

In Freudenberg's statistics, after excluding the fatal cases (4.2 per cent), we find 92 per cent. improved, 55 per cent. cured, 37 per cent. definitely improved, and 8 per cent. failures. Why should there not be a greater uniformity of results? Is the operative technique, or the instrument at fault? Turning to the instrument, we find the one of Freudenberg much preferable to that of Bottini, as has been very frequently pointed out. But there are several very evident weaknesses in even the former instrument. In the first place, since there is the greatest difference as to size, shape and condition among hypertrophied prostates, it is unreasonable to expect one single cautery blade to be suitable for all. An incision which is sufficiently deep for a medium-sized hypertrophy may be wholly inadequate for a very large one, and positively dangerous for the small fibroid forms. Then, again, one lobe is often very greatly enlarged while another is only slightly so. Are we, then, to give each the same depth of cautery incision? I have in my collection of autopsy specimens several prostates with small but very obstructive middle lobe enlargements, where the ordinary Freudenberg and Bottini instruments would have penetrated beyond the capsule and perhaps into the rectum.

It is very evident, then, that an instrument with several easily interchangeable blades of graded sizes would be a decided improvement.

There are two other defects in Freudenberg's apparatus which, while apparently trivial, are of considerable importance. The first is in the shape of the beak of the instrument as now constructed. The traction necessary to hold the beak up against the prostate during an operation will often pull it into the urethra. This is due to the fact that the beak meets the shaft at such a wide angle (or at such a slope—see Fig. 7) that even moderate traction causes it to ride over a median bar (for example) and slip into the prostatic urethra. The dangers of this accident are not small. Indeed, it has occurred several times, and has been responsible for several deaths, the cause being division of the membranous urethra, extravasation, hemorrhage, etc. In order to be certain that the beak of the instrument is against the prostate, and has not slipped into the urethra, Freudenberg has wisely advised that a finger be inserted into the rectum to determine its location before an incision is begun.

I have carefully followed this practice for the past two years, and have thus prevented several accidents, for in numerous instances have I found that a little steady traction (as in an operation) would draw the beak into the urethra. But this safeguard is not always sufficiently accurate, for while it is comparatively easy to feel the tip of the instrument turned downward toward the trigone, one can not often feel the beak with sufficient certainty when the instrument is turned to make a lateral cut, as one of my own cases demonstrated to my sorrow. (Freudenberg's instrument was being used.) The forefinger of the right hand was inserted into the rectum, and the tip of the beak definitely located to be in the bladder. The rotation was made for a lateral cut, and with the finger still in the rectum

cal construction and easily remediable by bringing broader areas into contact, was one which frequently led to great trouble both on account of the heating of the handle and the insufficiency of the electrical current which reached the cautery knife.

Recognizing more and more during two years' work with Freudenberg's instrument the drawbacks referred to, and especially, feeling the need of blades of different size, the writer finally consulted the Kny-Scheerer Co. of New York,<sup>1</sup> during April, 1901, with reference to the construction of an instrument which would, if possible, fill all the requirements. After considerable experimentation we have produced, we believe, a satisfactory instrument, the construction of which is thoroughly explained by the accompanying cuts.

Figure 1.

traction put upon the instrument to draw the beak up snugly against the prostate. The beak was not felt to slip into the urethra, but before beginning the cautery incision another careful examination with the finger (which was kept in the rectum during the entire operation) was made and did not reveal any slipping of the beak. Despite all these precautions (which happened to be unusually carefully taken in this case) an incision of 3.5 cm. was followed by a gush of blood from the

As seen in the illustrations, the form of Freudenberg's instrument is adhered to (Fig. 1), the only changes being in its having four interchangeable blades, a beak of different angle, a connecting handle with more extensive contact surfaces, and a few minor changes in construction. By a very simple device, the simple elevation of a sliding bar on the rotary wheel, one blade may be removed and another inserted (Figs. 2 and 3). The sliding bar working on a spring holds the rod contain-

Figure 2.

Figure 3.

meatus, and a perineal section done under cocaine revealed a ruptured membranous urethra, and extravasated blood behind the triangular ligament. A timely operation saved his life, but it brought very forcibly to my mind the need of a beak which would not slip into the urethra, one more nearly at right angles to the shaft.

The other defect, at times quite disagreeable, was that the handle of the instrument would often become so greatly heated as to burn the hand of the operator, and sometimes to prevent his turning the contact screw to break the electrical current. Examination soon showed that this was due to bad contact. This connection was made by a flat surface coming against a cylinder, resulting in a linear contact, insufficient to conduct the high current necessary to heat the instrument without itself getting hot. This defect, while merely one of mechani-

ing a blade firmly attached to the screw mechanism by engaging the circular groove near its outer end (Fig. 4). We have had four blades constructed as shown in Fig. 5. The smallest having an elevation of .8 cm., the second 1.2 cm., the third 1.7 cm., and the fourth 2.1 cm.

Figure 4.

Blade No. 3 corresponds to the one usually found in Freudenberg's instrument, and is the one most generally used, while No. 2 is useful in small hypertrophies, and No. 4 for the very large. Blade No. 1 (the smallest) was constructed mainly to complete the set, and with-

1. My thanks are due to Mr. Charles Farner, mechanic, for valuable help.

out any idea of much practical value. I have been surprised, however, to find it very useful in several cases, which will be given in detail further on.

The change in the shape of the beak has been of very great comfort. The new beak (Fig. 6) can not possibly slip by the prostatic orifice into the urethra with all the outward traction which may be put upon the instrument during the operation, whereas with the Freudenberg instrument (Fig. 7) one must be constantly on his guard lest this occur. The right-angled character of the beak does not make it any harder to introduce, in fact it seems to ride over a high median bar with greater ease, having more the shape of a prostatic catheter.

The changes made in the attachment handle of the conducting cable, as shown in the diagrams, consists merely in bringing larger surfaces in closer contact. These have completely done away with the disagreeable overheating of the contact screw, which constantly occurred before.

Figure 5.

During the past five months I have used this instrument on sixteen cases, and have amply proved it to be practical, and one, I think, that has overcome many of the defects to be found in Freudenberg's instrument.

We will give in abstract a few illustrative cases, but before doing so it may be well to state the measures we take to determine before operation the size, shape and character of the prostatic enlargement, and consequent selection of the blade to be used, and the length of the cuts.

Besides a systematic general physical examination,

Figure 6.

each and the length of blade chosen. They demonstrate, I think, the *raison d'être* of the new combined cautery incisor, and its practical value. The work with this instrument being of recent date unfortunately prevents our showing the ultimate result obtainable, as several months must generally elapse before the full effects of the operation are secured.

CASE 1.—J. N. M., aged 71, had been suffering with urinary trouble for 4 or 5 years. During this time urination became steadily more difficult and more frequent until he now voids every one and one-half hours, night and day.

Examination showed slight, but definite, enlargement of the prostate, which was much harder than normal, but not nodular. The cystoscope showed a small median transverse bar and a

Figure 7.

noting particularly the condition of the arteries, a very careful local examination is made as follows: *Rectal examination*, noting: the size, shape and consistence of the prostate; the relative enlargement of the two lobes, the thickness of the prostate as revealed by the finger in the rectum, and a sound in the urethra (determining in this way the thickness of the hypertrophy in the median portion); the adnexa of the prostate, vesicles, glands, rectal mucosa, etc. *Bladder examination*: 1, with catheter, noting the location, depth and character of prostatic obstruction, with residual urine, the capacity of the bladder and its tonicity; 2, with the cystoscope, noting: (a) the size, shape, location and character of intravesical prostatic hypertrophy (especially as to the condition of the median portion, whether a bar or a rounded or pedunculated lobe, and its elevation

slight intravesical projection from the lateral lobes, but there was really very slight intravesical enlargement of the prostate. With a finger in the rectum a very slight increase in thickness over the normal was felt between it and the instrument in the prostatic urethra. The bladder, however, showed very definite effects of obstruction, viz., considerable trabeculation and pouch formation, a residual urine of 90 c.c., and a capacity of only 250 c.c. *Remark*: We evidently had to deal with the so-called small sclerotic prostate, furnishing moderate but definite obstruction and a bladder hypertrophied and somewhat contracted. The very slight enlargement and the small amount of prostatic tissue beneath the urethra made us afraid to use Freudenberg's instrument. A thorough prostatectomy would have been impossible, and as the case appeared to be in need of the Bottini operation, we persuaded the patient to wait until the arrival of our new incisor, so that we might use a smaller blade.

On May 31, 1901, a Bottini operation was performed with blade No. 2 of our instrument, which blade seemed to suit the case exactly. Three cuts were made: one posterior, 2 cm. long; and two lateral, the right 2.5 cm., the left 3 cm., at right angles to the posterior (see diagram). The instrument was used at a high heat; time, about 1 cm. to the minute; the operation done under control of a finger in the rectum. It was evident that a larger blade would probably have cut through the posterior capsule of the prostate.

The convalescence of the patient was as usual: difficult urination for the first few days and after that a gradual improvement. The ultimate result was a complete relief of prostatic obstruction, micturition free, residual urine nil.

CASE 2.—F. E. B., aged 34, presented himself on June 30, 1901, complaining of bladder trouble. The patient had had nocturnal incontinence of urine up to the age of 14, and after that he always voided urine much too often. Seven years ago cystitis developed, and a calculus was discovered and removed by suprapubic cystotomy. The fistula did not heal till eight months afterward, and cystitis has persisted ever since. On admission he passed his urine about 6 times a day, generally with pain referred to the neck of the bladder.

*Examination.*—Patient was a rather neurotic young man. The urine was cloudy, acid and contained phosphates, pus cells and bacilli. The prostate examined by rectum was slightly enlarged, considerably indurated at the upper end of each lobe. The seminal vesicles were both indurated and closely bound to the upper end of the prostate. The fluid expressed from the prostate and the vesicles by massage shows pus cells. A rubber catheter was passed into the bladder, but met some constriction of the prostatic orifice. The patient had just voided, but a residual urine of 220 c.c. was found. The bladder capacity was 500 c.c. The cystoscope showed a marked trabeculation of the bladder wall, a considerable thickening of the interureteral bar, and behind it a deep pouch in which was a considerable collection of sand and small calculi, white in color.

Examination of the prostatic orifice revealed a definite thickening of the median portion in the form of a transverse bar, and behind it a fairly deep bas fond. There was no intravesical enlargement of the lateral lobes, but the entire prostatic orifice was irregular and showed numerous granulations.

*Remark.*—Although the patient was a young man, he had unquestionably an enlargement of the median portion of the prostate, which was causing considerable obstruction to urination, as shown by the trabeculation and pouch formations in the bladder and the presence of 220 c.c. residual urine. The prostate was undoubtedly chronically inflamed, but the enlargement, while probably inflammatory in origin, was unquestionably causing trouble, and in our opinion demanded a Bottini operation. The prostate, however, was so small that it was out of the question to use the ordinary Freudenberg blade, so that patient was asked to wait until our instrument could be completed. In the meantime he was put upon bladder irrigations and given urotropin internally.

On Sept. 13, 1901, examination showed considerable improvement in his cystitis, but the urine was still purulent. There was still 220 c.c. of residual urine present. Cystoscopic examination showed an improvement in the inflammation of the mucous membrane, and much to our surprise the considerable mass of small calculi which was previously found had disappeared. A very careful search was made with the cystoscope, but no calculous deposit could be found anywhere. There was still present the definite transverse median bar with a pouch behind it, and the bladder wall was still trabeculated. Accordingly the Bottini operation was performed, using blade No. 1 and making a single posterior cut through the median bar 2 cm. in length. There was some hemorrhage following this cut. After the operation the patient experienced considerable discomfort for a few days, but since then his condition has continued to improve.

It was intended to make three short cuts (see diagram) through the median bar with the small blade, but a burning out of some of the electrical connections in the hospital after the first cut had been made prevented the others being made.

Now two months have elapsed since the operation, his condition is much improved and the residual has dropped to 150 c.c. Unless this disappears soon we shall make the two other cuts through the median bar as originally intended.

CASE 3.—G. T. H., age 73, admitted Sept. 9, 1901, complaining of prostatic hypertrophy and catheterism. Urinary difficulty began soon after the age of 50, but did not get severe until about 1 year ago, when micturition became quite difficult, and the patient had to get up two or three times at night to urinate. About 10 months ago he had to resort to a catheter, which he has used ever since, being unable to void any urine naturally. He has had several attacks of inflammation of the bladder, and both testicles have been the seat of abscesses during the last 6 months. He now catheterizes himself regularly three times a day, and suffers very little discomfort, but the passage of the instrument is often quite difficult.

*Examination.*—Strong, healthy-looking man, arteries slightly thickened, small nodules in both epididymes. Prostate markedly enlarged, about the size of a large orange, left lobe much larger than the right. The median furrow is deflected towards the right. The upper end of the prostate is hard to reach. The consistence is smooth, soft, not tender. Urine is acid 1014, not very cloudy; microscopically, numerous pus cells and bacilli.

Cystoscopic examination showed a very marked intravesical enlargement of the left lateral lobe, considerable enlargement of the median bar, and a lesser enlargement of the right lateral lobe, with a small rounded mass between the two lateral lobes in front. There was a very deep bas fond behind the prostate, and the bladder was very much trabeculated and inflamed. The blade of the Freudenberg instrument would have been perfectly suitable for this case.

A Bottini operation was done under chloroform, blade No. 3 being chosen. This blade is of the same size as Freudenberg's.

The posterior cut was 3.25 cm. long, right lateral cut 3.25 cm. long, left lateral cut 3.5 cm. long (see diagram). The operation was done under the control of the finger in the rectum. Hemorrhage moderate and patient in splendid condition at end of operation; 1000 c.c. submammary infusion of salt solution was given as a prophylactic against uremia.

The patient made a rapid convalescence, required catheterization only three or four times after the operation, and very soon began to void urine naturally. His condition since then has steadily improved, until now the interval between urinations is every two hours during the day and longer at night. His general health has improved wonderfully, he has gained 12 pounds in two months, and will apparently get a good result.

CASE 4.—E. W. S., age 63, admitted Sept. 13, 1901, complaining of enlarged prostate catheterism. Urinary trouble began four years before with difficulty and frequency of urination, which at times had become so bad he had to use a catheter. For the past three months has had to use catheter three times a day, and has not been able to pass any urine naturally. For the last four years the patient has suffered from diabetes mellitus, which has been somewhat controlled by dieting.

*Examination.*—Large, healthy-looking man. The rectal examination showed a very large hypertrophied prostate, left lobe apparently larger than the right, consistence firm, but not nodular. Urine removed by catheter was acid, slightly cloudy, contained both albumin and sugar, and under the microscope showed pus cells and bacilli. After six days of diabetic diet there was barely a trace of it to be found. A rubber catheter entered the bladder with difficulty. The bladder tonicity was

only moderately good, and the capacity about 500 c.c. The cystoscope showed a marked intravesical enlargement of the left lateral lobe, which projected into the bladder as a large rounded tumor, a moderate enlargement of the median portion, and a very slight enlargement of the right lateral lobe. Behind the prostate was a very deep bas fond in which the ureters could not be seen. The bladder was considerably trabeculated and inflamed.

September 19, 1901, Bottini operation was made, under cocain and morphia. On account of the considerable size of the prostate, blade No. 3 was used, and as the left lateral lobe was much larger than the right, a much longer incision was made on that side. The posterior median cut was 3.5 cm. long, the left lateral 3.5 cm., and the right lateral 2.5 cm. (see diagram). Time taken, 1 cm. to 1 minute. Instrument was used at a white heat. There was very little hemorrhage following operation, and very little pain caused, the anesthetic being very efficient. Immediately after the operation the patient voided urine naturally, and has never been catheterized since. For the first few days there was considerable vesical spasm.

On Oct. 2, 1901, thirteen days after the operation, the following note was made: Patient now passes his urine about every two hours in a large stream and without pain. There is no dribbling; residual urine 140 c.c.; urine, acid, quite purulent, pus cells and cocci present. Sugar is still present in considerable amount.

In a letter dated Nov. 5, 1901, the patient reports that he had not used a catheter since operation, that he urinates once during night and four times during the day, that his residual urine is less than 50 c.c., that micturition is free, and the vesical inflammation greatly improved.

CASE 5.—J. P. A., age 71, was referred to me by Dr. Finney on Sept. 28, 1901. The patient gave a very long urinary history, which began with difficulty in micturition 11 years ago, when a stone was found and removed by a surgeon through a suprapubic opening. For two years following this he had a suprapubic fistula, which was finally cured by his taking up catheter life in 1895. Castration was then done by another surgeon, and several weeks later another suprapubic to remove another stone. During the next year the stones reformed and were crushed by a third surgeon. After that he was free from pain for a while, but had to use a catheter. Stones soon appeared again, and during the next twelve months four separate litholapaxies were done. In 1897 still another surgeon did a suprapubic operation and removed stones, and at the same time removed by means of the rongeur forceps a moderate-sized median lobe which was still present (despite the castration). After this operation, for the first time the patient was able to go without the use of the catheter, but micturition has been too frequent.

*Status Presens.*—Patient on admission complained of irritation of the bladder. He urinated every two hours during the day and twice during the night, but had no pain or discomfort during urination. Rectal examination: The outlines of the prostate were easily made out, and a little larger than normal. In the median line the prostate presented a slight but distinctly abnormal rounded mass. The lateral lobes were apparently much atrophied and sloped away from the central mass, which replaced the median groove and notch. The whole diameter of the prostate was half as large again as normal, the consistency of the lateral lobes soft and flabby. Urine was acid, 1022, containing pus cells, bacilli and cocci.

Cystoscopic examination: Rubber catheter met an obstruction about 7 inches from the meatus, but a silk one was passed with ease. Patient had just voided, but 320 c.c. of residual urine was found in the bladder. Cystoscope showed two fairly large stones in a pouch behind a considerably hypertrophied interureteral bar. The mucous membrane of the bladder was much inflamed, but not markedly trabeculated, and there were no ulcers to be seen. Examination of the prostatic orifice

showed a small but definite transverse median bar behind which there was a shallow bas fond. There was no intravesical enlargement of the lateral lobes to be seen, and there were no sulci between the lateral lobes above, nor between them and the median bar.

*Remark.*—The castration had removed the enlargements of the lateral lobes, but the median lobe persisted, after that. The removal of this through a suprapubic opening allowed the patient to urinate without the use of a catheter, but there still remained a definite transverse bar at the median portion (the base of the middle lobe) which continued to act as an obstruction, 320 c.c. of urine remaining in the bladder after micturition. It was evident that after litholapaxy a Bottini operation should be done to remove this obstructing bar, but the amount of tissue felt beneath the instrument in the urethra was so slight that it was decided to use the smallest blade of the incisor.

On Oct. 17, 1901, under cocain and morphia, litholapaxy was done, and followed by a Bottini operation. The crushing and evacuation of the stone was easily accomplished after placing the patient in the Trendelenburg position. The largest stone was one inch in diameter. All fragments were sufficiently crushed at the first introduction of the lithotrite, to be removed by evacuation afterward. After all debris had been removed, the bladder was washed clean, cocain again inserted into the bladder and urethra, washed out after three minutes, and a Bottini operation performed. For this purpose blade No. 1, which in this case was 8 mm. high, was used. Three cuts were made through the median bar, each 1.5 cm. long, one cut being in the median line posteriorly, the other two cuts were made at angles of about 50 degrees to the median cut (see diagram). The operation was done with the forefinger of the right

hand in the rectum pushing the prostatic bar into the angle of the beak of the instrument. This was done because it was feared that the length of the beak in the bladder would so depress the trigone and bar of the prostate that the knife would not penetrate it for its full depth.

The patient stood the operation well; anesthesia quite good; very little hemorrhage. He was unable to void his urine afterward, and had to be catheterized three times in the next 24 hours. When seen a week after the operation he was voiding urine quite freely and the residual had dropped from 320 to 150 c.c. and he was already feeling greatly improved. He attended his office on the fourth day after the operation.

Condition one month after operation: Steady improvement, residual now 125 c.c., sometimes more. Bladder is still large and weak in tone, but condition improving.

November 21, 1901, bladder capacity is 400 c.c., tonicity considerably improved; residual, however, 175 c.c.

CASE 6.—J. A. B., age 70, admitted Oct. 18, 1901, complaining of enlarged prostate and catheterism. His urinary trouble began ten years before with difficulty and frequency, which soon became so aggravated that he began the use of a catheter, which he has used continuously up to this time. For the past seven years he had been unable to void any urine naturally, and when admitted passed a catheter about every two hours during the day and about every three hours during the night, using a very large rubber catheter. Examination showed a very large, hard prostate and a considerable dilatation and lengthening of the urethra just in front of the prostate. The cystoscope revealed a moderate-sized stone in a pouch behind the prostate, and a very much inflamed and trabeculated bladder. There was present a considerable intravesical outgrowth of the prostate, which appeared as a collar-shaped enlargement, both lobes and the median portion being hypertrophied, the left projecting farthest into the bladder. Behind the median bar was a deep pouch. The bladder capacity was rather small. The urine, which was obtained always by catheter, contained many red blood-corpuscles, pus cells and bacilli, and was acid in reaction.

On Oct. 23, 1901, litholapaxy was done under chloroform. The operation was begun under cocain, but chloroform had to be used on account of pain. The largest diameter of stone

grasped by the instrument was 2 cm. The crushing and evacuation were both difficult on account of the great hemorrhage caused and the trabeculated condition of the bladder. Patient stood the operation well and was very much more comfortable afterwards, but still required catheterization.

On Oct. 26, 1901, a Bottini operation was done under cocaine, 4 per cent., and a hypodermic of  $\frac{1}{4}$  gr. of morphia. Blade No. 3 was chosen as the proper size for all of the cuts, of which three were made, one posterior through the median bar 2.75 cm.

long, a right lateral 2.5 cm. long, left lateral 3 cm. (see diagram). The duration of cuts was about 1 cm. to 1 min. and a high heat was used on the blade.

There was very little hemorrhage following the operation, and immediately afterward the patient voided urine.

ing the operation, and immediately afterward the patient voided urine.

Patient made a rapid convalescence, voiding his urine freely immediately after the operation and never after required catheterization, although he had led a catheter life for seven years.

On Nov. 7, 1901, 12 days after the operation, he reported that he was rapidly improving, that he passed his urine once every three hours without any straining and was free from pain. A catheter passed four weeks after operation finds no residual urine, and the cystitis considerably improved.

CASE 7.—J. M. D., age 73, admitted October, 1901, complaining of hypertrophy of the prostate and catheterism. Urinary trouble began about seven years ago with difficulty of urination. A little later retention of urine became complete. He then began to use a catheter, and has had to use it ever since, never being able to pass any urine. He has remained in fairly good health, has had very little inflammation of the bladder, and now has to pass a catheter about every four hours, twice during night. Increasing difficulty in introducing the instrument of late has driven him to the operation.

*Examination.*—Large, healthy-looking man, arteries slightly thickened, heart and lungs apparently normal. Small hydrocele of right side. Prostate very much enlarged, about the size of a moderate-sized orange, lateral lobes about equally enlarged, contour round, smooth, consistence hard. Seminal vesicles indurated, but not nodular. A rubber catheter met obstruction  $9\frac{1}{2}$  inches from meatus. The bladder capacity was 400 c.c., tonicity rather poor. Urine acid, slightly cloudy, and contained pus cells and bacilli. The cystoscope showed a very markedly trabeculated bladder with numerous small pouches. Behind the prostate was a very deep bas fond in which the ureters could not be seen. There was considerable inflammation of the mucous membrane. Both lateral lobes and the median portion were very much enlarged, presenting a large collar-shaped intravesical hypertrophy around the urethral orifice, which projected well out into the bladder cavity. Growing from the upper portion of the lateral lobes, especially the left, were numerous small villi, which floated in the fluid but caused no hemorrhage. There was no ulceration of the surface of the prostate.

October 28, 1901. Bottini operation, cocaine and morphia. Blade No. 3 was chosen. Four cuts were made, one in the median line posteriorly across the median bar 3.25 cm. long, one right lateral cut 3 cm. long. Through the left lobe two cuts were made, one lower oblique at an angle of about 75 degrees to the median posterior cut 3.25 cm. long, and an upper oblique cut at an angle of about 130 degrees to the posterior median cut also 3.25 cm. long. The direction of these cuts is best shown in the accompanying diagram. Patient stood operation well. There was very little hemorrhage, and anesthesia was quite good. Time occupied was about 1 cm. to 1 min. For the

first 24 hours after operation the patient voided urine with considerable ease, after that it became more difficult, the bladder becoming irritable and catheter had to be used for six days. After that patient began to void without the use of a catheter.

Condition three weeks after operation: Patient voids about every hour, but sometimes two and one-half hours elapse between urinations. The vesical inflammation is improving, and its capacity increasing gradually. The catheter on which he depended for seven years has not had to be used for two weeks.

On November 21, 230 c.c. of urine was voided at a time with an interval of two and a half hours. Urination was fairly free, stream large. Residual urine was 10 c.c.

December 13, patient voids urine about six times in 24 hours, in amounts varying from 150 to 210 c.c.

CASE 8.—S. M. A., age 56, admitted Oct. 28, 1901, complaining of frequency of urination. His prostatic trouble began two and a half years before with difficulty of urination. Since then micturition had become gradually more frequent and difficult, and one year before he had begun the occasional use of a catheter. On admission he complained of a dull pain at the beginning of urination, which occurred every two or three hours during night and day. He had suffered considerably with inflammation of the bladder.

On examination patient was found to be a man in fairly good health. The prostate on rectal examination was found to be slightly enlarged, soft in consistence, contour smooth and round, and both lobes of about the same size. The seminal vesicles were not indurated. The urine was cloudy, specific gravity 1017, pus cells and bacilli were present in considerable number. A rubber catheter passed with some difficulty, owing to obstruction in prostatic urethra. Residual urine 185 c.c. (another examination three weeks later showed a residual of 375 c.c.). The bladder capacity was between 500 and 600 c.c.; tonicity fair. Cystoscope showed a small median bar which joined, without intervening sulci, with two very slight intravesical enlargements of the lateral lobes. Behind this median bar was a definite, but not very deep, bas fond in which the ureters lay rather close up to the prostate. The interureteral bar was considerably enlarged and behind it was a rather deep pouch. The posterior wall of the bladder was very greatly trabeculated, and between some of these trabeculae small round and oval openings were seen which connected with extravescicular pouches. About 1 inch behind the left ureter a very considerable diverticulum with a large round opening into the bladder was seen, and the cystoscope was introduced into this for some distance, and a cystoscopic examination of the diverticulum made. With a finger in the rectum and the cystoscope in the urethra the amount of prostatic tissue between them was found to be very little thicker than normal; more than in Cases 2 and 5, but much less than usual in prostatic enlargements.

The rectal examination and cystoscopic examination both showed only a slight enlargement of the prostate, but the considerable residual urine and the marked evidences of obstruction as shown by the trabeculation and pouch formation in the bladder wall made it evident that there was considerable hindrance to urination. The prostate was so small that prostatectomy would have been very difficult, although the patient was in splendid shape for any operation, and the ordinary Freudenberg instrument would undoubtedly have been dangerous to use on account of the danger of penetrating the capsule of the prostate. Blade No. 2 of our instrument appeared to be the proper size to be used, with cuts not longer than 2 cm.

On Nov. 20, 1901, a Bottini operation was performed under cocaine and morphia. Blade No. 2 was used in accordance with the cystoscopic and rectal examinations as stated above; five cuts were made as shown in the diagram. One median posterior and two oblique on each side, one at an angle of 75 degrees to the median posterior, and the other at an angle of 120 degrees. Each cut was made 2 cm. in length. Patient stood operation well. There was very little hemorrhage from the cautery cuts. The catheter was not required after the operation.

On the day following the operation there was a temporary suppression of urine, which was relieved by subcutaneous infusions and digitalis.

December 13, patient has done well. Urine is voided freely, often 300 c.c. at a time. Residual urine, 0. Cystitis is improving. Result is excellent.

#### SUMMARY.

Reviewing the eight cases reported in full above, we find four cases (3, 4, 6, 7) in which blade No. 3 was used. All of these were fairly large hypertrophies of both lateral lobes and median portion, and were suitable cases for Freudenberg's instrument.

In two cases (1 and 8) blade No. 2 was used. In both of these the prostate was very slightly larger than normal, as shown by rectal, instrumental and cystoscopic examinations, but in both of these cases there was

Figure 8.

marked evidence of obstruction and the cases urgently needed operation. In both cases, however, incisions made with Freudenberg's instrument would probably have penetrated beyond the confines of the prostate, but the operations were performed safely with blade No. 2 of our instrument.

In two cases (2 and 5) blade No. 1 was used. In both the obstruction was caused by a very small median bar, associated with complete atrophy of the lateral lobes (after castration) in one case and lobes of normal size in the other. In these cases the amount of tissue

Figure 9.

beneath the instrument was so small that we feared to use even blade No. 2. In another case (not here reported) the enlargement consisted in two very large lateral lobes, associated with a complete absence of median bar, the urethra skirting the posterior surface of the prostate and the amount of tissue between the rectum and a sound in the prostatic urethra being very small. In this case we used blade No. 3 for the lateral lobes and blade No. 1 for the posterior cut.

I have not as yet used blade No. 4, and hardly think it will often be necessary except to attack a single very great hypertrophy of one lateral lobe. I have, however,

seen several tremendous general hypertrophies in which it would have been necessary.

As to the efficacy of the Bottini operation, of which I was myself at first very skeptical, my experience (now of 41 operations) forces me to testify decidedly in its favor.

In 41 cases I have had 3 deaths, all men in very bad condition before operation, and 2 with pyonephrosis. Fifteen patients were over 70 years of age, 3 over 80, and among these there have been no deaths, and all but one have been cured of the prostatic obstruction. Of 13 patients who had to use the catheter, there is only one

Figure 10.

who still requires it, and this one is considerably improved. Some of my cases are of too recent date to show the ultimate results, and these I will reserve for a later publication. I am still, however, of the opinion (from an experience of 15 prostatectomies) that in certain cases, *e. g.*, men between 45 and 60, in good condition, and with easily enucleable enlargements, a complete prostatectomy is a very safe operation, and certain as to lasting results, though I must say the effects of the

Figure 11.

Bottini operation seem to be also permanent. Time, careful study of cases (especially with the aid of the cystoscope) and long-continued observation after operation can alone determine the applicability and the limitations of the principal operations for the treatment of prostatic hypertrophy.

In closing the paper I can not too strongly urge that the Bottini operation should be performed in accordance with the character of the prostatic obstruction as found by exhaustive examination as previously outlined. There is no doubt but that a perfunctory performance of the operation with one blade for all cases, and one cut

directed posteriorly and one laterally on each side, while perfectly satisfactory in a large number of cases, is insufficient in some and dangerous in others.

As shown by the writer in another paper,<sup>1</sup> when a decided median lobe (more or less pedunculated) is present, the ordinary operation is entirely inadequate as the posterior cut will generally pass to one side of the median lobe and leave it to continue its obstructive work—see Figs. 8, 9, 10.<sup>2</sup> If, however, the cuts be so made as to pass obliquely across the base on each side of this projecting lobe,<sup>3</sup> I have shown that this lobe may be dropped back out of the way (Fig. 13) and a rapid atrophy induced by thus cutting off most of its blood supply (as in diagrams, Figs. 11, 12, 13). This has been abundantly proved in five cases, some of which were entirely unaffected by the usual three incisions and the prostatic obstruction immediately removed by the incisions described above.

Figure 12.

Figure 13.

The cases outlined above serve to show the selection that may be made in some forms of hypertrophy as to the size of blade to use, and as to the length of incisions, their number and direction. No two cases are alike, and each should be a study unto itself.

As a rule the usual three incisions—one posterior and two lateral—are entirely sufficient for most cases; especially those of moderate hypertrophy, where with more incisions the danger of causing a slough, too large to be passed per urethram, is considerable. The same rule applies to middle lobe cases: unless the median enlargement is considerable the single posterior incision should be preferred as free from all chance of completely amputating the median lobe, and leaving it to act as a foreign body in the bladder.

In the choice as to the length of incision and the size of the blade to use there is considerable latitude and it should always be based on a careful study of the conditions present, and controlled by rectal touch.

1. Monatsberichte der Urologie, December, 1900.

2. To be more explicit: Fig. 8 shows the Y-shaped urethra, which is present in these middle lobe cases, and Fig. 9 shows how a metal instrument that has been introduced into the bladder will pass to one side the middle lobe, and not remain on top of it. Fig. 10 illustrates a case in which I performed the usual Bottini operation with no result, and a subsequent suprapubic cystotomy showed the posterior cut on one side of the middle lobe as shown in Fig. 10.

3. This is accomplished by the following maneuvers: Introduce incisor, draw beak up against anterior portion of the prostatic orifice, rotate instrument 180° (hugging the prostatic orifice all the while). This will bring beak into sulcus to one side of middle lobe. Carry the rotation 45° further and beak will lie obliquely across the base of the middle lobe, ready for the first cut, Fig. 11. By reversing these movements the cut on other side of middle lobe may be similarly performed, and then the two lateral cuts made, Fig. 12. The result is shown in Fig. 13, a diagram from an autopsy specimen.

**Prize for Essay on Hypodermic Use of Morphin.** Dr. J. B. Mattison, Medical Director of Brooklyn Home for Narcotic Inebriates, offers a prize of \$400 for the best paper on the subject: "Does the Habitual Subdermic Use of Morphia Cause Organic Disease? If so, What?"

## LICHEN PLANUS HYPERTROPHICUS.\*

DAVID LIEBERTHAL, M.D.

Professor Dermatology, Illinois Medical College; Dermatologist to the Michael Reese Hospital and United Charities' Dispensaries. CHICAGO.

There are a number of names for this affection: Lichen simplex chronicus circumscriptus; lichen verrucosus, lichen corneus, etc., most of which are appropriate to this morbid process. In the last two decades it has been the subject of lively discussion, inasmuch as some cases of this description do not yield to the administration of arsenic, others do not show any typical lichen papules, but only the verrucous patches are characteristic of this disease and hence there arises serious doubt whether in these cases we have really to deal with a true lichen-planus process or with an atypical form of mycosis fungoides—A. Neiser, Deutscher Dermatologen Congress, 1894—or with a lichenization of a localized pruritus in the sense of Brocq. Thus further, Kaposi has named cases of this appearance keratosis verrucosa papillaris.

Now, this question as to the identity of these with lichen planus has lately been answered in the affirmative, after consideration of their clinical and anatomic features.

In view of the rare occurrence of this form of lichen planus, I wish, in the course of my remarks, to cite cases which will partly illustrate the subject in question and besides bring out some pertinent points.

**Symptoms.**—The affection is characterized by rounded or bean-like, oblong, irregularly outlined plaques of a bluish-red, brownish-red or violet color. They are flat, warty elevations sharply defined and their surface bears numerous whitish, or grayish, bran-like, firmly adherent scales; besides, there are on the surface deep point-like and larger depressions into which horny plugs are implanted. The consistence of these lesions is quite firm and they are elevated to half an inch and free from hair. Neither spontaneously nor on pressure is pain felt, but there is severe itching and especially so on the site of the patches. Besides these, there are sometimes found brown pigmented spots and atrophied areas.

In certain of the cases typical lichen papules are seen in the neighborhood of the hypertrophied lesions, or on other parts of the body, besides corresponding lesions on the mucous membrane of the cheeks in the form of white nodules or tender white reticula. In other cases no elementary lesions whatever are found. The seat of the affection is, in the majority of cases, the anterior and, to a lesser degree, the lateral aspects of the tibia, and especially the middle third. Sometimes varicose veins are present. Inasmuch as the lesions show a tendency to aggregation and frequently a band-like arrangement in the direction of the long diameter of the limb, there may exist a relation to certain cutaneous nerves. Regionary glands are sometimes found to be enlarged.

This affection mostly occurs in males over 40 years of age. Its course may be very chronic. Thus, Lion describes a case of a female patient, 43 years of age, in whom it had existed since childhood, and showed besides the hypertrophied areas typical lichen papules. The diagnosis is not difficult for those who have seen a case, inasmuch as all the cases present much the same appearance.

**Diagnosis.**—It must be differentiated from the fol-

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee of the Section: W. T. Corlett, L. Duncan Bulkley and W. L. Baum.

lowing conditions: Warts, which are more cleft and have no scales on the surface; tuberculosis verrucosa cutis, in which there is found an inflammatory halo and foci of pus accumulations; lichenoid eczema, which is never of so great extent; typical cases of mycosis fungoides, where there are other characteristic symptoms, even if the tuberculous patches should not be broken down, or the atypical form of Bazin, in which the tumors developing without preceding manifestations (*d'emblée*) soon break down into putrid fungous areas; keloid, which is smooth and painful on pressure; the discs of the keratomatous stage of sarcomatosis cutis multiplex hemorrhagica, which show a depressed central portion and no scales; ichthyosis verrucosa, which dates from childhood and has a generalized distribution, and lupus hypertrophicus, where the affection dates from childhood, presents a red basis and in the neighborhood there appear brownish-red firm nodules deeply implanted in the skin.

*Etiology.*—The etiology of this affection is obscure. Although we observe in most cases an arrangement of the lesions corresponding somewhat to the course of

traumatin 10 per cent., or the latter alone. J. Schuetz reports good results in these cases from the local application of plastrinull of mercury and arsenic. But there are other cases, where no other than surgical interference will produce results. In one of my cases a recurrence took place in spite of the total removal of the verrucous patches with the thermocautery. I am under the impression that those cases which present, besides the verrucous patches, typical lichen planus elements give better prospects in treatment than those where hypertrophic areas only are present, and especially so when the former are in larger distribution.

I wish at this juncture to report two cases which represented this affection.

CASE 1.—Male, aged 45, German, manufacturer. Father of four healthy children, and comes of healthy stock. He smokes considerably and drinks some beer; has had no venereal or skin disease and knows of none of his relatives being afflicted with such. About six years before, presenting himself at my office he had an attack of rheumatism in his arms and legs, lasting about eight months. About a year later he commenced to suffer from severe itching, especially on the abdomen and extremities, and soon afterwards noticed pimples in these

Fig. 1.—a, Horny plug; b, dilated duct of sweat-gland filled with horny mass; c, infiltration cells arranged in rows; d, irregularly shaped projections.

Fig. 2.—Arrangement of the infiltration cells in rows within the threadlike and elongated papilla. a, Horny plug; b, greatly broadened stratum granulosum; c, imperfect keratinization.

the cutaneous nerves, there seems to be but slight probability of a nervous causation. The severe itching often present can be explained in the same way as in other inflammatory conditions. Inasmuch as it occurs chiefly on the lower limbs where the circulation is somewhat impeded, and more so in middle life, it would not be too much to suspect the changed lowered circulation in the locality of being an etiologic factor, especially when we further consider that in a large percentage of the cases considerably developed varicose veins are noted. In some cases, injury preceded the development of these warty growths.

I shall describe the histopathology in connection with the microscopic findings of a specimen from one of my cases.

*Prognosis.*—The prognosis as regards the general health of the patient is favorable, although some patients suffer from intense itching, especially while they rest. This much can be said concerning the curability. Some of the cases have yielded readily to the administration of arsenic in the form of Asiatic pills; sometimes this combined with the local application of chrysarobin in

localities and about two years ago the lumps on his legs appeared. Different remedies were applied with varying results until his family physician referred him to me. On his first visit, August, 1900, I found the following condition: He was well built; of medium stature with a well-developed panniculus adiposus; of dark complexion with brown hair, blue eyes; body not very hairy; organs of chest and abdomen apparently normal, and no alteration in the nervous system. Urinalysis revealed nothing pathologic. As soon as the patient had undressed, he began vehemently to scratch himself, especially on the abdomen.

On the forearms, abdomen, penis, serotum, sacral region and legs there were numerous, brownish, flat papules of polygonal outline and waxy appearance, solitary and in groups, with here and there larger lesions of more roundish outline and more bluish color, especially on the extensor surface over the wrists, and on the glans penis. On the anterior aspect of the right tibia, about its middle, was an irregular, oblong, warty patch about one inch long and three-fourths of an inch broad and corresponding with the direction of the tibia. Just below this was another roundish plaque of the size of a dime and in the line of prolongation of the first. On the anterior aspect of the left tibia, somewhat higher than the middle, was a node

of the size and shape of a bean. These were elevated about one-fourth of an inch above the skin level, and presented all the other features of lichen planus hypertrophicus, but were not very itchy.

Closely around these warty elevations were seen numerous typical lichen papules and also dark-brown, pigmented spots. These were also found on other affected parts. On the mucous membrane of the cheeks, which was the seat of leucoplakia, lichen planus symptoms could not be observed. The patient, not residing in the city, was referred back to his family physician with the diagnosis and the suggestion to administer Asiatic pills in increasing dose up to the time of noticeable improvement, and then to gradually decrease; the local application of oleum eadinum 20 per cent, alternating with Unna's ointment of carbolic acid and corrosive sublimate, was also recommended.

In January, 1901, I saw the patient again. All the symptoms had disappeared, but there were areas of pigmentation at the sites of the former lesions and shallow depressions at the site of the verrucous patches. I advised the continuance of two pills daily for a few months. I regret that the patient would neither give his consent to have pictures taken, nor permit the excision of a portion for histologic examination.

CASE 2.—This patient presented quite different features. Male, American, 47 years old. Manager of a musical instrument establishment. Married and has three healthy children. His mother died at 30 from unknown cause. His father, who

internal organs nor urine revealed anything abnormal. The entire skin, with the exception of that on the lower limbs, was normal, as was also the mucous membrane of the mouth and urethra. The anterior aspect of each tibia was the seat of bluish-red elevations, extending one-fourth of an inch upward, and from the size of a pea to that of a penny; they were sharply defined and had irregular outlines, with all the other characteristic signs of an hypertrophied lichen. There were seven on the right tibia, and four on the left. The lesions on both sides were arranged quite regularly one above the other. On top of these patches were roundish, bloody excoriations. There were no typical lichen papules visible near these agglomerations nor anywhere else. For nearly eleven months I tried in vain every conceivable internal and external medication. The itching was at times subdued, but there was no noticeable change in the eruption. In March, 1898, I removed these elevations with the thermocautery. When healing was nearly completed, he left the city and I did not see him until November, 1899, when he consulted me for an urticaria on the face, which lasted about two weeks and was probably due to glycosuria. The urine showed about one-fourth per cent. of glucose, but there was no acetone and under appropriate diet the glucose disappeared. At that time I incidentally inquired

Fig. 3.—a, Horny plug; b, stratum granulosum broadened; c, elongated and broadened epithelial projection; d, infiltration.

is still living at 70 years of age, is in good health, but had a red scaly skin affection of the face a few years ago, which lasted about two months and then disappeared without leaving any trace. The patient at the age of 12 had swollen glands of the neck, and at 20 he had an attack of gonorrhea. He had no other venereal disease or other illness, but suffered a fracture of the distal portion of the right ulna.

He is of active temperament and regular habits. The present affection began about seven years ago, when he was quite an enthusiastic bicycle rider. Returning from an evening ride his legs began to itch considerably, to which he paid but little attention until a few days later, when they became reddened and swollen. He consulted a physician, who prescribed a soothing application. The swelling soon subsided, but the itching continued. He did not notice any pimples. He changed physicians frequently and used all sorts of advertised remedies, but without relief. On the contrary, he grew worse and scarcely a year after the first symptoms occurred, lumps appeared on the front of the lower limb, where all the former symptoms were. These increased gradually in number and size. The itching was always present and especially at night, when his scratching caused bleeding.

I saw the patient for the first time in April, 1897. He was rather tall, strongly built and with a moderately developed panniculus, had light complexion and blue eyes. Neither

Fig. 4.—a, Dilated intercellular spaces, showing infiltration of cells.

about his legs and learned that they were worse than ever before. On examination, I found that not only were the lesions previously removed, much larger, but there were also numerous other warty growths. On the inner side of the right tibia there was a plaque about the size of a quarter, where formerly there was one the size of a dime; it was irregular and had a hilus on its upper border. A few lines below was a roundish one the size of a dime. About one-third of an inch below this, on the site of six original lesions, was an oblong band-like plaque  $2\frac{1}{2}$  inches long and nearly 1 inch broad; its upper part resembled a mushroom and the whole plaque appeared like a longitudinal section of a moderately filled gut. About an inch below, was a lesion nearly the size of a dime. On the outer side of the right tibia were two lesions, one lobulated, about the size of a half-dollar, and about  $2\frac{1}{2}$  inches higher was the other, kidney-shaped and slightly larger than a nickel with a hilus on its upper side.

On the outer side of the left tibia near the crest there were two large patches, the upper resembling a four-leaved clover, the other like an inverted letter L. Midway between and just behind the two was a roundish one the size of a nickel. Below the left knee at the upper margin of the middle third of the tibia was a plaque the size of a dime. A year later, in November, 1900, I saw this patient again and the pictures here presented were taken. The lesions above described were all still

present besides new ones from the size of a pea to that of a dime, mostly situated in the neighborhood of the old plaques. These are marked X on the pictures. All the eruptions had irregular outlines, mostly segments of circles, indicating their origin from coalescence of roundish lesions. They were sharply defined, warty, raised about one-third of an inch with a gradually sloping periphery; they were of a grayish-violet color and presented bloody excoriations. They were beset with fine grayish-white, flaky adherent, bran-like scales and had holes or depressions from the size of a pin's point to that of a split pea, into which scaly masses extended. They were quite firm to the touch, not painful, but produced excessive itching as testified by the bloody excoriations. There were no elementary lichen lesions and no atrophic spots. I now obtained his consent to excise a piece from one of the larger growths. Having read J. Schuetz's article in the *Archiv. für Dermatologie und Syphilis*, 1900, in which he strongly recommended plasmectom of mercury and arsenic for this affection, I tried it, carrying out the directions with painstaking accuracy, but without result. During these four years, I had looked carefully and also requested the patient to watch for pimples—elementary lesions—but found none. In April, 1901, I again saw him, when he reported less itching and his condition better. I observed on the inner side of the right tibia, near the inner side of the largest plaque, a group of about eight typical papules closely arranged. On calling his attention to

only slight colloid degeneration. The pigment is not increased. The cells of the basal layer were well shaped, being flattened only in places. The papillae are densely infiltrated, considerably elongated; and some are thin and irregularly shaped. The capillaries, lymph spaces and blood vessels are dilated. The infiltration cells in the papillae are largely arranged in rows. In the subpapillary layer, the infiltration is irregular and quite dense; the blood and lymph vessels are dilated and here and there is an island of sclerosed connective tissue within a heap of infiltration cells. In this and the deeper layers of the corium, there are found groups of small spindle-shaped cells, also slender reticula of connective tissue containing cells, the latter resembling the structure of a lymphatic gland.

In the deeper layers of the corium the infiltration is scanty, being chiefly around the blood and lymph vessels and the sweat glands, the ducts of some of the latter being dilated. Plasma cells were not found. Hair follicles and sebaceous glands were not present in the sections. The anatomic findings correspond to those of lichen planus, but are more highly developed.

*Summary.*—The question now in regard to the presence of typical elementary lesion can thus be summarized: In some cases there is a more generalized eruption; in some only a limited number, and in still others none are present in addition to the warty plaques. In my second case typical lichen planus papules were only

Fig. 5.—a, Duct of sweat-gland; b, irregular projections; c, spindle cells.

Fig. 6.—a, Small spindle cells in groups; b, sweat-glands; c, upper and medium part of corium; d, sclerosed connective tissue.

these he said he thought these were not pimples, but scratch-marks, because they itched intensely. Having him stripped, I could find no other elementary lesions, but on the mucous membrane of his left cheek just behind the angle of the mouth I saw two somewhat acuminate white papules scarcely as large as a pin's head. During the whole time of my observation I noticed neither any varicose veins nor any nervousness; he did not lose flesh and is now as active as ever.

In November, 1900, when the pictures were taken, a piece was excised from one of the largest plaques, fixed and hardened in alcohol, embedded in celloidin, cut, and stained in hematoxylin and eosin.

The microscopic examination shows the following conditions: Stratum corneum hypertrophied, with here and there a well-stained nucleus. Within this layer are seen the ducts of the sweat glands, broadened and filled with horny masses. Prolongations of this layer in the form of broad plugs dip downward into the thickened spinous layer. These plugs are not confined to hair follicles, as can be readily seen. The stratum granulosum is broadened, especially just below the horny plugs. The stratum spinosum, which is thickened, shows widened intercellular spaces; this is more true in the deeper layers, in which are seen infiltration cells penetrating from the papillary layer. In the spinous layer vacuoles are found, but

detected four years after I first saw him. We may infer, however, from the history and course of the disease that lichen planus papules may have been present at different times and been overlooked by the patient. That the verrucous lesions did develop from such, there seems to be no doubt, inasmuch as their development was evident from the coalescence of smaller ones. Sometimes, as v. Duering and Gebert emphasize, transition from the plain to the verrucous form can be observed. In other words, clinical as well as histologic considerations justify the interpretation that these verrucous plaques are a special manifestation of the lichen planus process. From the above considerations we draw the following conclusions:

1. The absence of typical elementary lesions does not justify the exclusion of hypertrophic lesions from the class lichen planus.
2. The elementary lesions will be found at one time or another during the course of the affection.
3. This verrucous manifestation of the process may be due to circulatory derangements.

4. For cases in which elementary lesions are also present, and especially more extensive in distribution, prove serviceable at the periods when typical elementary lesions are also present.

The camera slides which I had the pleasure of demonstrating, as well as the photomicrographs, were prepared by Dr. C. T. Gramm.

The literature of the subject is fully covered by the reports of the last fifteen years: *Archiv f. Dermatologie und Syphilis*; *British Journal of Dermatology*; *Journal of Cutaneous and Genito-Urinary Diseases*; *Monatshefte f. Practische Dermatologie*.

103 State Street.

#### DISCUSSION.

DR. C. W. ALLEN, New York City—I was interested in the differential diagnosis which the Doctor brought out so very well. It is not always an easy matter to make a diagnosis in these cases, and we have to run through in our minds the various things mentioned, and little differential points are of great assistance. In treating warty hypertrophic lichen of late, I have been using the curette a good deal, and have been surprised to find how very soft the tissue is, deep in under the crusts and warty tissue. I think it is a good plan sometimes to curette the border if the patch is advancing. The border will usually be found, especially deep in underneath, as soft as that of lupus erythematosus, but I do not think it is always known to dermatologists even, how soft the latter may be at the advanced border.

DR. DOUGLASS W. MONTGOMERY, San Francisco—I would not like to make a diagnosis of lichen of any form simply on the ground of lichen-like papules, because you can get papules like lichen in almost any itchy disease of the skin. Lichen itself is a rare disease in my experience.

DR. H. G. ANTHONY, Chicago—Taking all the symptoms of the case together there can be no doubt that what the Doctor described as lichen hypertrophicus is the same as the lichen cornuus of the French, and that differs in no wise from lichen planus, except that it is in an advanced stage. In this form of lichen, the lesions look like the burning end of a cigar, that is, ash-colored scales on the surface of a red background, shining through the scales here and there. As to the treatment of this condition, a good deal has been said, especially by authorities in New York, on the value of large doses of mercury, and I think it may be looked upon as established that mercury in all its forms is of value in lichen planus. I have been informed that lichen rubber planus cases would tolerate considerably more than an ordinary individual. The mercury should be given in large doses, and it does not matter what preparation you use.

DR. W. T. CORLETT, Cleveland—As the illustrations were passed around I had in mind two diseases, one a form of lichen, the other sarcoma. I have never had a case identical with this although I have had lichen verrucosus, in which the lesions were very large and much more numerous. I think the Doctor has drawn his conclusions well; I am inclined to agree with him in the diagnosis. In regard to the treatment of this affection, many years ago I was strongly impressed with the value of arsenic in this special form of skin diseases, first because I had never used it, and second, because Mr. Jonathan Hutchinson recommended it, and for a good many years I believed that good results might be obtained from arsenic, although I was unable to obtain them myself. In lichen planus, although I have given arsenic in increasing doses, I have never obtained the slightest benefit, so far as I have observed. I have not pushed mercury, therefore I can not say as to that, I believe there is no drug we can give internally that will have any effect in cutting short the disease. On general principles I generally give iron, strychnin, and other tonics.

DR. L. DUNCAN BULKLEY, New York City—As the subject of the use of arsenic in lichen planus has been spoken of, I wish to mention a very striking case in a man aged 35, where the use of arsenic pushed immoderately in the hands of others had greatly aggravated the eruption, which I have observed in other cases. In this instance the eruption, which had become so severe on the hands as to incapacitate him for work, yielded very rapidly and perfectly to the chlorate of potash and nitric acid treatment, recommended by Bergh, of Norway, over twenty-five

Outer side of left limb.

the prospect of treatment seems better than for those which present the verrucous growths only.

5. In some cases only repeated surgical interference will remove the affection and arsenic is more likely to

years ago. This I have employed constantly since that time, and in many cases, with satisfactory results. The hypertrophic conditions, as described in the paper, are not very rare in lichen planus. I have had a number of cases exhibiting lesions much like those shown in the colored drawings of Dr. Lieberthal. In some instances they were the main feature of the case, in others there was also an abundant eruption of small, flat papules. In this condition internal treatment is relatively indelicate, and strong local applications are needed, such as Unna's salve of carbolic acid and bichlorid in diachylon ointment. Beginning with a milder strength, a few grains to the ounce, I have sometimes increased it until a blistering or a suppurative action has resulted.

DR. R. R. CAMPBELL, Chicago—In the several cases of lichen planus which have passed under my observation I have been in the habit of administering arsenic and in each case have had most satisfactory results. In one case, which was typical and was seen by Dr. Anthony in consultation with me, I administered arsenic, pushing it as rapidly as circumstances would permit, and the results obtained in this case were most gratifying. We had the satisfaction of following the case for some time, about the diagnosis of which there could be no question.

DR. H. C. SUMNEY, Omaha—I have used arsenic in Fowler's solution up to 35 drops, four times a day. A case had been treated by chlorid of potash and nitric acid. It was an undoubted case of lichen planus, part of it hypertrophied, on the arm and limbs, and we obtained very gratifying results finally with arsenic, working it up to 35 and 40 drops of Fowler's solution. Dr. Baum saw the case. We used the solution of arsenic hypodermically:

DR. M. L. HEIDINGSFELD, Cincinnati—In looking over the microphotographs, and also the lantern slides of yesterday, I was impressed with one point which Dr. Lieberthal has failed to bring to our particular notice. In many of the more favorable sections there is a dense massive wall of cellular infiltration, which is sharply confined to the papular layer of the epidermis, and extending to, and slightly involving the lowest layers of epidermal cells, to such a degree that a sharp borderline between this infiltrate and the epidermis is lost, and the columnar character of the lowest layer of cells is no longer preserved. These are very constant features of lichen ruber in its earlier stages when infiltration is well marked, and to my knowledge is not encountered to any similar degree in any other process, so that the microscopic appearance is very characteristic, if not actually pathognomonic. I can concur in the statements of those members who have seen favorable results from the administration of arsenic. I can not recall a single case that has not been promptly and materially benefited by this agent. I have used the hypodermic administration almost exclusively, employing one-gram doses of 10 per cent. cacodylic acid, or 2 to 3 per cent. sodium arsenate. I recall several cases where Fowler's solution and Asiatic pills had been administered internally, even to the degree of inducing distressing symptoms, without positive results, whereas the institution of hypodermic administration was followed by prompt material improvement.

DR. D. LIEBERTHAL, Chicago, in reply—Dr. Allen is right in calling attention to the soft border which really can be observed in some cases. The plaques increase by spreading in the periphery, and in their beginning as long as they are quite new they are rather soft and with increasing stage of development the consistence increases. These conditions are substantiated by the pathologic findings. In regard to the presence of typical elementary lesions, it is more difficult to make a diagnosis when they are wanting. In my second case I would not have made a clinical diagnosis as readily if I had not seen such cases during my service under von Hebra in the Vienna Policlinic. The reason why I entered into details and especially so with the differential diagnosis was because in the text-books the account of this manifestation occupies about four lines. Dr. Anthony's remark about the similarity of some lesions to the effect produced by the red of the burning cigar gleaming through the ashes is correct. Concerning the administration of mercury, I can state that I used it in my second case quite actively, but

without results. Dr. Corlett, I think, spoke to the point. The plaques look very much like sarcoma, and I stated in my paper the differential diagnosis between these. The remarks of Dr. Bulkley in regard to the administration of arsenic are very worthy of note. It is true enough that in a large number of cases of lichen planus, arsenic will not produce the effects desired. The effect of arsenic depends frequently on the freshness of arsenical preparations. Sometimes we have to try one after another. Furthermore, the mode of administration is important. In some cases the patient can take arsenic by mouth, in others not and we have to apply it subcutaneously or per rectum. Another important point is to see the patient frequently enough, to ascertain the limit of tolerance. I have found it expedient in every case where arsenic is administered to use an astringent as well and one of the best is iron, as was correctly remarked by Dr. Corlett. Unna's ointment sometimes proves of great value, especially if, after it is rubbed in, a woolen cover is applied and the patient is kept in bed.

#### NOTES ON RECENT CASES OF EXTRA-GENITAL SYPHILITIC INFECTION.\*

L. DUNCAN BULKLEY, A.M., M.D.

Physician to the New York Skin and Cancer Hospital, Consulting Physician to the New York Hospital, Etc.

NEW YORK CITY.

At the meeting of this Section last year<sup>1</sup> I called especial attention to syphilis as a non-venereal disease, as observed in marital syphilis, hereditary syphilis, and that acquired by means of innocent extra-genital infection; the latter in social and industrial life, in the care of children, and in professional care of the sick. The instances where the disease has been in some manner innocently acquired, which have fallen under my personal observation and care, now number many hundreds, and there are constant additions. The subject of marital and hereditary syphilis is a large and interesting one, but must be illustrated on another occasion. At present it is desired to call attention to the rather frequent occurrence of extra-genital infection, as indicated by the relatively considerable number of cases which have come under my care in private and public practice during the past year, or rather since Jan. 1, 1900. On former occasions I have reported many instances of this form of infection, and the total number of cases which have come under my personal observation now amounts to about two hundred.

During the period mentioned, 21 instances of extra-genital syphilitic infection have come under my care, 12 in private practice and 9 in public; to these might be added 2 cases of chancres of undoubted venereal origin in unusual localities, 1 on the lower portion of the anterior abdominal wall, and 1 within the urethra. Many more cases have also been seen casually; for instance, at a recent meeting of the New York Dermatological Society a case was presented with chancres on the bridge of the nose, and another with one on the ball of the thumb; such are not included here. The following shows the location of the extra-genital chancres in these cases: Lip, 9; finger, 5; anus, 2; hand, 1; nostril, 1; hard palate, 1; tonsil, 1; eyelid, 1. Of these cases, 16 were in males and 5 in females; curiously enough all the 12 cases seen in private practice were in males, while in public practice there were 5 females and 4 males.

*Chancre of the Lip.*—Of these, 3 cases were seen in private practice and 6 in public. This location of in-

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee of the Section: W. T. Corlett, L. Duncan Bulkley and W. L. Baum.

1. JOURNAL A. M. A., April 6, 1901.

fection is undoubtedly more common among the poorer classes, who are more careless or reckless as to the dangers from the poison than are those in the easier walks of life, who have a healthy horror of the disease. Most of the cases presented no peculiar interest; 5 were on the upper lip and 4 on the lower; 6 were males and 3 females. They all gave about the usual history of a cold sore or abrasion of the lip, which failed to heal and gradually developed a hardened patch. In almost all of the cases the patients came for treatment because of the appearance of a more or less severe general eruption, and my experience has been that rarely are these cases recognized until the advent of constitutional symptoms. It is well known, however, that long before this the local sore is giving off an intensely contagious secretion, and the profession and the public need to be aroused to the danger of neglecting, on the lips or elsewhere, suspicious sores which refuse to heal. In one case in private practice the infection was proved rather conclusively to be due to smoking the pipe of a man suffering from syphilis, who had mucous patches in the mouth. In 2 other cases in private practice it was traced to barbers, the sore beginning just below the vermilion border, at a point injured while being shaved. Several cases were attributed to the kissing of people with mucous patches. In all the cases there was marked adenopathy, either just below the chin or on one or both sides of the jaw.

*Chancre of the Finger.*—Of the 5 cases of chancre of the finger, 4 were in physicians, with also a fifth physician, who received an infection on the ulnar side of the back of the left hand during an operation.

One of these cases, which has only very recently come under my care, has had such severe and distressing results that it merits particular description. Five years ago, Dr. —, aged 47, injured the skin near the nail of the right index finger, with a nail cleaner, and very soon after the part was exposed while treating a chancre of the vulva. A few weeks later there was a slight sore on the end of the finger, under the nail, which in a week or two became a rather painful, small ulcer. The nature of the trouble was not suspected until a general macular eruption appeared, and under anti-syphilitic treatment the eruption disappeared very promptly and the finger healed; at the same time the severe general malaise, with fever, ceased. Five or six months later subjective symptoms appeared again, but as there were no external manifestations of syphilis, the cause was not suspected, and specific treatment was not used. For the two years following the patient was miserable, long periods of rest and much treatment for stomach and other troubles being necessary. There was a severe and steadily increasing pain in the lumbar region and about eighteen months after the finger was infected he found it difficult to go up and down stairs and to get into a carriage; the patient's legs dragged and he felt weak and tired, and yet there was no suspicion of the cause, it being all attributed to overwork.

After retiring one night in March, 1898, two years after the infection, he became delirious and for the following five days was insane. It was then suspected that the cause was syphilis, and iodid of potassium administered freely. During the next three months there was increasing motor disturbance in the lower limbs, until in June when on attempting to leave the bed the lower limbs were found to be totally paralyzed; this paralysis lasted for about five months. Power in the limbs then returned very slowly and he can now

walk with difficulty with the aid of two canes, but he can not stand for more than a minute. The bladder and rectum are both partially paralyzed, requiring the use of the catheter and high rectal injections. He is at present improving rapidly under very active mixed treatment.

In the case of another physician, aged 38, who was infected beneath the left thumb-nail in May, 1884, the most severe and disfiguring tubercular lesions have appeared upon the face and within the mouth, quite incapacitating him for work; this condition has resisted treatment and recurred in an agonizing manner. There were never any severe early symptoms and he was married in June, 1888. The following year a healthy boy was born; the child is now in perfect health and well developed. His wife has had no more children, nor any miscarriages. Under very careful treatment the lesions, for which he has recently come under my care, are healing nicely, but a large amount of scar tissue will be left.

In another case of a physician, aged 33, infection took place, on the site of a wart which had been injured, on the back of the right forefinger, during the delivery of a dead child from a supposedly syphilitic woman. The earlier symptoms of constitutional syphilis have been moderately severe, but have yielded well to treatment. The other cases are still more recent and little can be said in regard to the severity of the disease.

*Chancre of the Anus.*—Two interesting cases of chancre on the side of the anus have been seen recently, both discovered only after the appearance of the general eruption. In 1 of them, a young man aged 28, seen in consultation, there was good reason to believe that it was due to improper practices; but in the other there was no possibility of such a cause, and mode of infection has never yet been ascertained. In a similar case, which I have already reported, the infection was traced directly to soiled bathing drawers, but in this instance no such cause existed. It must have been contracted in a watercloset, from secretions left on a paper, or possibly on hotel bed linen, for he traveled extensively. The case is worthy of special mention because of the severity of the symptoms and the length of time which elapsed before the true nature of the trouble was recognized.

Mr. J., aged 46, has long had what was called "itching piles," and has been obliged to scratch the anal region. On Dec. 27, 1900, he noticed a raw or ulcerated spot to the right of the anus, which persisted until he presented himself, April 6, 1901. Within two weeks after the ulceration was noticed there was a general eruption, quite papular in character, which was still present when seen. This had been diagnosed as chicken-pox and other conditions, but its true character had never been recognized, partly, perhaps, because of the character of the man and the absence of exposure through intercourse.

When first seen there was an abundant large, flat, papular syphilide over the body, limbs and face, which was unmistakable. The lips and mouth were also the seat of the most profuse mucous patches, producing great distress. Recognizing the nature of the eruption, I sought for a long time before finding the seat of infection. The penis was free from disease, there was no evidence of a present or past primary sore on the fingers, in the mouth, or on any part of the body, until the anal region was examined. There was then found on the right side, extending somewhat into the opening,

a partly healed, superficial ulceration, with quite a hardened base; this had existed for over three months and only palliative ointments had been used, but these served to prevent much annoyance. During all this time he had been totally without specific treatment, and had mingled freely with others, in his home and elsewhere, without the slightest suspicion of the immense danger from the profuse discharge given off by the raw mucous patches covering the lips and much of the buccal cavity. The only wonder is that there are not more cases of extra-genital infection from some of these neglected cases.

The progress of the case under very active specific treatment was remarkable. The eruption faded very promptly, the mucous lesions in the mouth healed shortly, as also did the sore in the anal region, and in a month there were only some stains to indicate the nature of the former trouble.

*Chancre of the Hand.*—Five months before Dr. T., aged 55, consulted me. he had noticed a sore on the back of the right hand, on the ulnar side. This had occurred after an operation on a patient where there had been much pus, and, as there was much inflammation in the sore on the hand, with the formation of abscesses on the arm, which were opened, the real nature of the infection was not recognized. Some five months later he noticed the general macular papular eruption, which had faded materially before I saw him, and when he presented himself he had also a very considerable amount of mucous patches on the tongue and lips. There had been no other infection, and he certainly had not been exposed venereally. The delay in the appearance of the eruption was probably accounted for by the severity of the ordinary pus infection already alluded to; this has been known to retard the development of the constitutional signs of syphilis.

*Chancre of the Nostril.*—Mr. D., aged 34, was sent to me for the diagnosis of a general eruption which had appeared first about ten days previously and had rapidly developed, covering the entire body and limbs, including the palms. He was surprised and indignant when the eruption was pronounced syphilitic, for he was a married man and had led an extremely virtuous and careful life. There was certainly no primary lesion on the penis, although the general large, papular syphiloderm existed there; neither could any site of infection be found anywhere on the body, limbs or elsewhere until attention was directed to a soreness in the right nostril, which almost occluded it. It was then learned that for fully six weeks preceding he had suffered from what he supposed to be a cold, having much trouble with the throat, and a soreness deep in the right nostril, which he considered a "cold sore." He had taken no specific treatment, as the nature of the trouble was not suspected until the advent of the eruption.

On making careful and deep examination, with the throat specialist, who had suggested the consultation, we found the right side of the septum nasi the seat of a superficial ulceration, running back nearly an inch, and half an inch or so wide. It was rather hard, with quite sharply-defined edges and a gray pultaceous floor. There was considerable swelling of the turbinated bones and some mucous patches around them. The submaxillary glands on the right side were much enlarged. The source of infection could not be traced. In another case of chancre in exactly the same location, previously reported, the poison was probably from the patient's

grandchild, whom she had cared for, and who soon after died with hereditary syphilis.

*Chancre of the Hard Palate.*—Mr. W., aged 50, a lawyer, was brought to me by his family physician on account of a general macular eruption which had appeared a week or two previously. There was no question in regard to the diagnosis, but the same difficulty as in the other cases presented itself. How had the infection been acquired? He was a man of high moral character, who certainly had not been exposed through sexual congress. The same search was made for the site of entry of the poison, the patient being stripped, and for a long time no local sore was found on any part of the body or in the throat. Attention was then directed to a certain soreness which he had long experienced on the roof of the mouth. A well-defined ulceration was there found, in the median line about one inch from the front teeth, oval in form, and partly healed, but with a superficially ulcerated base; the submaxillary glands on each side were found enlarged. The source of infection was never ascertained, but supposed to be through eating in public places.

This patient has faithfully carried out the treatment for over a year, and has experienced as yet no serious symptoms from his disease. The eruptions faded rapidly and the ulcer on the roof of the mouth healed quickly, under active specific treatment, and his health, which had suffered greatly, improved in a remarkable manner, he regaining many of the pounds he had lost.

*Chancre of the Tonsil.*—Miss McG., aged 30, was brought to me by her physician, with a very profuse, large papular syphiloderm, developed principally about the mouth and face, but with also some scattered lesions on the neck, chest, and elsewhere. The throat had been sore for some weeks and on examination the left tonsil was found to be greatly enlarged, distinctly hard to the touch and with tolerably well-defined ulceration over most of its surface; the submaxillary glands on that side were large and hard. No source of infection was discovered.

*Chancre of the Eyelid.*—Mrs. —, aged 32, had a sore on the edge of the lower right eyelid, extending well over its inner surface, for the treatment of which she applied to one of the eye clinics. After the appearance of a general eruption the nature of the trouble was recognized, if not before, and under proper constitutional treatment the eruption disappeared and the sore on the eyelid healed. When she came to me there was really only the scar of the chancre on the inner surface of the right lower eyelid, with some adenopathy on that side, and some remains of the already faded eruption. No history as to the source of infection could be obtained, and no suggestion as to the source of the virus could be made.

While these cases present nothing that is striking or peculiar, it was thought desirable to place them on record as instances of the accidental and innocent acquirement of syphilis aside from coitus, which are really more common than the general profession appreciates. While some of them were in physicians, who are known to be frequently exposed, over three-fourths of the whole number of cases were in lay people, who never appreciated the possibility of such an accident and who, perhaps, could not have protected themselves from it, even though aware of the danger to which they were exposed. By the repeated recording of such cases the profession and public will in time learn that syphilis is not always acquired through the act of coition, and

the stigma attached to a person infected will be in a measure removed.

## DISCUSSION.

DR. L. B. BALDWIN, Chicago—The articles I have written on the subject have been chiefly addressed to dentists. In looking carefully over the text-books of dentists in not one can I find any reference made to the contagiousness of the mucous patch. That struck me immediately. I had five cases of young practitioners attending the dental colleges in Chicago who were suffering from mucous patches. I have also had four cases where I could trace the infection of the patient directly to the dentist's chair. The greater number of chancre, as I have seen them, occur in the better classes, not in the poorer classes. I do not think the question of filth or habits have much to do with the possibility of acquiring a chancre on the lips or mouth or tongue, as I do not think the chances are as great in proportion as among the better classes. Dr. Rhodes asked if I had any cases of chancre of the tonsil. I had two, and gave them to Dr. Rhodes, who collected 32 others. The chancres occurred in physicians. I have seen three, one a physician in the West, who was suffering from chancre Dr. Baum saw with me. He had infected himself by turning a doorknob and lacerating the skin of the finger which caught in the door. He was treating several syphilis at the time. I think medical teaching should be such that the dentist could recognize a chancre or mucous patch. There is absolutely nothing on that subject demonstrated in the Chicago colleges, and the number of mucous patches and chancres that come to the dentist, thinking that the lesion is due to some trouble with the tooth or gum, is surprising. In the last year I have had sent to me by dentists 20 or 30 cases of syphilis. One dentist said to me that he had not seen a case of syphilis of the mouth in thirty-three years of practice in Chicago. I agreed with him that he had not seen it. The subject of extra-genital chancre is very interesting as a subject, but I do not consider it nearly as important as the subject of mucous patches of the mouth, which are so directly related to the initial lesion, and they are so much more common and last so much longer that I think the subject of mucous patches of the mouth should be taken into consideration with more thoroughness than is generally shown by the profession.

DR. L. E. SCHMIDT, Chicago—Out of a series of eleven last year one was a so-called hypertrophic chancre of the lip. It assumed the size and proportion of a small pear. It was situated in the median line of the lower lip and hung over like a large protruding part of the lip. Only in the center and lower portion was there a small, rounded, glazed, eroded surface having the typical appearance of a chancre on any other part of the body. I wish to state in this connection that the rash was present when the case came under my observation. A mercurial inunction treatment was started, but the tumor remained unaffected as far as the size and appearance went. Only when iodid of potash was administered in large doses in connection with the mercurial inunction treatment did the mass commence to disappear. Now, after four months' treatment, there remains no sign of any former lesion.

DR. D. W. MONTGOMERY, San Francisco—I would speak of an instance that occurred some time ago in my own practice where a grave error might have been committed by me in the diagnosis of a chancre of the tonsil. The man was coming from Bakersfield to Los Angeles. He looked in the glass at his throat on account of uneasiness there and found a lesion on the left tonsil that he took to be a chancre. He was not a physician but was a very intelligent man and knew something of medicine. He continued his journey to Los Angeles, saw two men there that are used to seeing chancres and they took it to be a chancre. He returned immediately to San Francisco because he wished to be under the charge of some one who would take permanent care of him and he wished them to see the sore as it then existed. He first saw it on Saturday; on Sunday two physicians in Los Angeles saw it; on Monday I saw it. I took it to be a chancre, and I thought of every possibility. The only thing about it was that it was not very hard, but some chancres are not very hard, and the lymphatic nodule under the jaw was not very marked nor very hard.

However, I took it to be a chancre, for it looked absolutely like one. I remarked what a beautiful photograph it would make as the man held his mouth open and depressed his tongue and one could look right down on the base. That forenoon he saw two other men, both of whom were used to seeing chancres, and they both thought it a chancre. We met in consultation that afternoon, and all three agreed that it was a chancre, but as we thought it would do him no harm we had better wait, and commenced to give large doses of tincture of iron. In three days it was vastly improved, and in seven days there was nothing left but an unevenness of the surface. I do not know what it was; there was cultivated from it a bacillus that was certainly not the diphtheria bacillus; it was larger and thicker than the diphtheria bacillus, and it was thinner and shorter than the leptothrix. I do not know what the disease was, but it was not chancre.

DR. C. W. ALLEN, New York City—I do not think the Doctor has proven at all that it was not chancre. Sometimes chancre is a very minute thing; sometimes in a few days it disappears.

DR. D. W. MONTGOMERY—He has never had any symptoms since.

DR. ALLEN—That is different. But a case like that should be observed very carefully for the next six to twelve weeks, or even longer to make sure, because not only may the chancre be almost nothing but the early eruptions be nothing. In my early days I took to Dr. Bulkley to have the diagnosis confirmed, a young man who had on his body twelve spots, by actual count. It looked like measles. That was the most eruption the man ever had. He had mucous patches, which confirmed the diagnosis afterwards, but it goes to show how very slight secondary cases of syphilis may be.

The primary lesion of syphilis is not always recognized; to illustrate that point, a young man came to me who had been to a celebrated hospital in New York and had the glands of his neck cut out. I do not know what they took the lesion for, but they made a long incision and excised all the glands of his neck and then they let him go. What they were operating on was a chancre, and these glands would have gone down beautifully under iodid of potassium if the gentlemen had recognized the trouble. But they do not as a rule have chancre in their minds. It is not surprising that the average practitioner who sees a little patch of syphilis here and there should let it escape him when he sees the sores in an unusual position. I would pass for a moment an illustration of what I believe to be a very unusual chancre of the lower lid. I have had chancres about the upper lid where there was a great amount of swelling, the eye being closed for some days and where there was going to be apparently a great loss of tissue, and it was surprising to see what little scar remained after the lesion healed. I have had a chancre of the lid in a position where it could not be accounted for unless in his work he had scratched the lid.

If Dr. Bulkley had not mentioned the fact that this physician had produced a lesion near the nail, and that was where the chancre was located, I might have thought he was describing the case of a physician I treated. My man had a little chancre on the knuckle, acquired in the practice of obstetrics. It is a statement sometimes seen in the books that lesions upon the hands are followed by more severe symptoms than the ordinary form of chancre upon the tongue. I have never been able to absolutely confirm that, although such cases as related by Dr. Bulkley with paraplegia, loss of consciousness, etc., would have that appearance. My man had every once in a while slight attacks of aphasia; he would be unable to talk for some time, then he would get all right and go off on a little trip, pushing the iodids and being all right again. But it is an interesting point as to whether these lesions upon the hands are followed by more severe symptoms than the ordinary syphilis we see.

I do not think the location has much to do with it. I do not think the data we are accumulating as to where the extra-genital chancre occurs, whether in women more than in men, has any bearing on the question. Where there is a solution of continuity and the virus enters there you get the chancres, and can get them on every susceptible part of the body. Large numbers appear to come from the barber shop; some come from

midwives. In the most recent case there had been a scratch from a diaper pin at the time of infection. Dr. Bulkley's case of family syphilis transferred from the baby to the grandmother is very interesting. I read of a case in the *Medical Record* where the baby first acquired a chancre from the wet nurse and gave it to the mother, a chancre of the nipple; the mother gave it to a second child and that child probably to the father, who had a chancre on the surface between the nares. There was the wet nurse, the child, the mother, another child and the father; so the whole family got it in succession in the same innocent way.

DR. D. W. MONTGOMERY, San Francisco—I forgot to mention that, in the patient I was speaking of, the lymphatic nodule quickly went down, which would never have occurred had it been syphilitic. There was no involvement of more than two lymphatic nodules and a sufficient time has elapsed between then and now to exclude specific disease. I do not believe it was a chancre.

DR. R. R. CAMPBELL, Chicago—I do not believe the occurrence of extra-genital chancre is quite as uncommon as we are led to believe; I think they occur more frequently than we have any idea of, but I do not think the diagnosis is made, particularly by the general practitioner, and the error is made from the fact that the general practitioner expects to find the secondary symptoms of the disease adjacent to the part in which the chancre is situated, which is not the case. It has been my experience that secondary manifestations usually occur about the chest and umbilicus. In cases of chancre of the lip that have passed through the hands of a general practitioner and come under my care, in talking the case over with the physician who has treated it previous to its coming under my observation he has invariably stated that he has had the case under observation from three weeks to four months and has not seen any secondary manifestations. To the question, Have you stripped the patient and looked him over for secondary manifestations? the answer is, "No." In almost every case of that character the secondary manifestation has been demonstrated, much to the surprise of the general practitioner who has treated it. The interest in cases of extra-genital chancre lies more in the mode of infection than from the fact of its being extra-genital. Four cases of chancre of the tonsil have fallen under my observation in the past year in which no visible means of infection could be traced or demonstrated, and in patients whom I had a right to believe had nothing to gain by holding back anything of interest to the attending physician. In another case, a chancre of the lower lip, the only history obtainable was from a drinking cup. The girl had been to a public dance and had drank from a glass which had been publicly used. I think if in the teaching and text-books more stress was laid upon the fact of the appearance of the secondary eruption about the chest and umbilicus, pointing out that the glandular enlargement is adjacent to the lesion and the secondary manifestations come first on the chest and abdomen, we would have more correct diagnoses of extra-genital chancres, and without the appearance of secondary manifestations I claim no man is justified in making a positive diagnosis of chancre and beginning anti-syphilitic treatment.

DR. D. LIEBERTHAL, Chicago—I believe it was wise and appropriate for Dr. Bulkley to bring out in his paper, from a scientific point of view, and more especially from a sociological standpoint, that millions of dollars are spent for sanitary progress and thousands of dollars for the prevention of disease, for instance, measles, and there is no reason why we should not call attention to the dangers which are menacing the public. I do not see why we should not try to make the subject more popular and not let it be said that the thing is not so bad because it can be conveyed only by sexual means.

DR. W. T. CORLETT, Cleveland—I have in mind now a young man I left at home who was probably infected from the barber. This point is of interest because the public should know, their attention should be called to the matter. This young man has a facial sore. He had a little pimple; he thought it was a hair, attempted to straighten or pull it out and the result is a

chancre on the cheek, at least I think it is. Sufficient time had not elapsed to make the diagnosis certain. I think it is well, as pointed out by Drs. Montgomery and Campbell, to wait until you are positive of the diagnosis. For eighteen years I have taught this to medical students, because I have seen the importance of it in coming in contact with cases treated by the general physician. So frequently a snapshot diagnosis of chancre is made; the patient is subjected to mercurial treatment; the result is the lesions disappear and years afterwards the question may arise as to whether or not the patient ever had syphilis. Those questions are so important that I think it is extremely necessary to impress upon students and others the advantage of waiting until a positive diagnosis can be made. I think it is no disadvantage in the way of treatment. Dr. Bulkley mentions a chancre resembling a "cold sore," which brought to my mind the fact that I have known a number of chancres following a cold sore. I have in mind a physician who a number of years ago had a sore on the lip. He had been treating a syphilitic patient and had a habit of stroking his mustache, with chancre as a result. With most physicians I find the chancre is on the hand, usually the right hand, not always at the border of the nail but somewhere on the index finger.

DR. L. B. BALDWIN mentioned the prevalence of syphilis in dentists. I think that is extreme. Some years ago we had a dental class with our medical class; the dental students were in the habit of coming to my office with venereal disease. Dental students in my experience are the most frequent victims of venereal disease and I suppose it is because they have absolutely no teaching. With our own students it is exceptional to have them come with venereal disease, but not so with the dental students because they are not instructed in regard to this dangerous eruption of the mouth. In regard to the severity of syphilis following extra-genital chancres, I agree with Dr. Allen that it has nothing to do with it *per se*; that the disease as such is usually neglected and goes on week after week and month after month without treatment and in those cases one expects to find and does find very severe constitutional symptoms following. In regard to the treatment of these neglected cases of course we all have special forms of treatment and we all probably have more than one method of treatment. I think in the treatment of syphilis we should not follow one routine; some by the mouth, some by injections, some by nitrate of silver injections. I think in severe cases nitrate of silver injections are by far the best because the most rapid and because there is an opportunity to push the drug without interfering with digestion. For many years I have used the salicylate of mercury, pushing it until the physiologic effects are produced and I only remember one instance where it was followed by an abscess.

DR. L. DUNCAN BULKLEY, in reply—I regard the points brought out in the paper of practical interest, because these cases come so unexpectedly, and if unrecognized, in families, they may produce much havoc. In regard to the relations of dentists to syphilis I think the physicians should give them every opportunity of knowing and recognizing the lesions of syphilis about the mouth. On two occasions I have lectured on the subject before the dentists of New York, exhibiting pictures and casts; it is very important that they should be able to recognize mucous patches. At the New York Skin and Cancer Hospital we had recently a course of lectures on syphilis by members of the attending and consulting staff, and the one on syphilis of the mouth, nose and throat, by Dr. Delavan, was repeated to a room full of dentists, cases being shown.

On the occasion of one of my papers on the dangers of syphilis in dentistry, before the New York Odontological Society, a physician present said, in discussion, that at the beginning of treatment of a patient with syphilis he sent him to the dentist, to have the teeth put in order, that there might be less danger of injury from the mercurials. I deprecated this practice, believing it to be better for the patient to suffer than to expose the dentist and others to the dangers of contagion; and I forbid the patient going to a dentist until I gave permission. When it is necessary for him to go I believe the dentist should

be informed of the condition of the patient, as should any other physician, and he can take the risk if he chooses, and take extra precautions against acquiring the disease or transmitting it to others.

Many of these cases of extra-genital chancre are curious and difficult of recognition. Few would suspect that this picture of chancre of the eyelid, exhibited by Dr. Allen, was of this nature; probably not two men in the medical section nor ten in the surgical section would so diagnose it. I was interested in Dr. Montgomery's case of suspected chancre of the lip. As I remarked before, these cases are sometimes very difficult of diagnosis, and opinion must sometimes be suspended for awhile. Some years ago I had a sore on the knuckle of my left hand that lasted for some weeks, which several of my confrères in New York regarded as a chancre, as I was much occupied with syphilis and had abundant opportunities for inoculation. After studying it pretty thoroughly I was satisfied that it was not such, and it healed under simple dressing, when the finger was splintered and irritation avoided. Some months afterward I had a node on the left tibia, which my friends agreed was of syphilitic origin, the result of the supposed chancre of the knuckle. But on investigation this was found to be the result of pressure on the sharp edge of my desk, as I sat writing, and this, too, disappeared under simple and proper measures without anti-syphilitic treatment. It is needless to say I never had any true signs of syphilitic infection. There is much need, therefore, of very great care in analyzing supposed cases of extra-genital chancre.

In regard to the location of the sore I may say that in my own practice, private and public, and in clinics and societies here and abroad, I have seen the primary lesion of syphilis situated on almost every portion of the body—about a hundred on the lips, dozens on the fingers and hands, many in the throat, etc. I would like to inquire of Dr. Baldwin if the 32 cases of chancre of the tonsil which he mentioned included the 15 which I reported some time ago?

DR. BALDWIN—No, they were cases collected in Chicago.

DR. BULKLEY—Since reporting these 15 cases I must have seen half a dozen or more other cases of chancre of the tonsil. They are not so very uncommon, and should not be overlooked; indeed, extra-genital chancre in various locations is far more common than is generally supposed, and accounts for the infection in many cases of old syphilis, where the sufferer is quite unconscious of the nature of the disease. I mentioned casually a case of chancre of the urethra to call attention to the possibility of having the sore in a location which may be overlooked; these cases are commonly regarded as gonorrhea. I also referred to an instance of chancre on the abdomen, just above the pubes; both of these were undoubtedly of venereal origin, but in locations not readily recognized.

In the case detailed of chancre in the region of the anus, it is very instructive to think what might have happened if the eruption had disappeared and the sore healed without the true nature of the disease being recognized. If the patient had later developed a syphilitic brain lesion, or one deep in the eye, or any serious later manifestation of syphilis, his physician would be thrown off guard by the fact that the man had not been exposed venereally and would have denied having had syphilis. The profession should be more on the lookout for these unusual cases, of which I have now seen about two hundred.

**The Campaign Against Malaria in Italy.**—The new law making the sale of quinin a government monopoly in Italy enables it to be sold at cost price, and brings it within the reach of the poor even in the remotest hamlets. The law also provides for the compulsory quinin treatment of malarial government and railroad officials and also of the employees of contractors, etc. Celli has recently discovered a large region in Tuscany where although swamps and anophedes abound and malaria is constantly being imported, yet it never spreads, and there has been no autochthonous malaria for twenty-five years throughout the region which was formerly a hotbed for the disease.

## TRAUMATIC ARTERIO-VENOUS ANEURYSMS OF THE SUBCLAVIAN VESSELS.

WITH AN ANALYTICAL STUDY OF FIFTEEN<sup>1</sup> REPORTED  
CASES, INCLUDING ONE OPERATED UPON.\*

RUDOLPH MATAS, M.D.

NEW ORLEANS.

PERSONAL OBSERVATION.

*Synopsis:* A case of traumatic (gunshot) arterio-venous aneurysm of the right subclavian vessels, involving the artery within the scaleni; division of the artery between ligatures placed on the first and third divisions; detachment of the anastomotic connection; lateral suture of the venous orifice; osteoplastic resection of the clavicle under eucaïn B. anesthesia; recovery, with partial loss of hand and forearm from arterial ischemia.

On September 8. Moise M., a young Acadian farmer, native of Rayne, Acadia Parish, La., was brought to me for treatment at the New Orleans Sanitarium. His attending physician, Dr. C. H. Power, Rayne, who kindly referred him to me and accompanied him to the sanitarium, gave the following particulars of his history and of the circumstances under which the injury was inflicted. We may premise the history of the injury by stating that he is a robust and exceptionally healthy man, aged 24, married. He is broad-chested, muscular, frugal, and temperate; very calm, collected, and courageous. In health he weighs 165 to 170 pounds, and is six feet in height. He is very industrious and active, and has always been engaged in outdoor pursuits. His past history and that of his parents, who are living, reveals no antecedents which bear upon his present troubles.

On Sept. 3, 1900, six days before his arrival at the sanitarium, and while attending a country festival near his home in Rayne, he became engaged in a personal difficulty at about 8 p. m. In the struggle that followed, he succeeded in throwing his antagonist to the ground, and, while holding him down with both hands, the latter drew a revolver from his pocket, and pressing the muzzle close to M.'s chest, fired.

Immediately after the shot M. felt the grip of his right hand relax and realized that his arm had been paralyzed. The spectators in the meantime parted the combatants, and M. was at once driven in a buggy to Dr. Power's residence, a distance of one mile. Though very weak, the patient stepped out of the buggy without assistance and walked a few steps into Dr. Power's office, when the latter saw him, about forty minutes after the shooting. After a hasty examination, sufficient to convince the doctor that the injury was of a very serious character, he applied a compress of iodoform gauze over the wound, and secured this in place with adhesive plaster. The blood had soaked through the patient's clothing and was still flowing out of the orifice of penetration when Dr. Power applied the compress. The bullet wound was small, however, and this moderate pressure succeeded in arresting the bleeding, though it was evi-

1. While this article is in press two additional observations of arterio-venous aneurysms involving the subclavian vessels have been reported by MM. Gallols and Piolet, Lyons, in a contribution on vascular injuries caused by simple fractures of the clavicle. ("Les déchirures vasculaires par fractures fermées de la clavicle," etc., in *Revue de Chirurgie*, Paris, No. 7, 21 année, July 10, 1901.) These observations, together with the case of Vasilyeff, in which there was ulceration of both vessels in abscess cavity, have reached me too late to be incorporated in the text, but will be found in the final table of the reported cases, which epitomizes the history of seventeen cases of arterio-venous aneurysms of the subclavian vessels, instead of the original fifteen tabulated up to the date of this meeting.

\* Read at the meeting of the American Surgical Association, held in Baltimore, May 7, 8 and 9, 1901.

dent by the rising swelling in the neck that a concealed hemorrhage was now progressing actively in that region. After a few minutes' delay the patient was helped to his buggy and conveyed to his home, a distance of one mile, where he was at once put to bed and an ice bag applied over the injured area. At no time did the patient lose consciousness, and it was not until he had reached home that he showed signs of great prostration and shock, which became intensified as the night advanced and the swelling in the neck and shoulder increased.

At the examination, made early that night at the patient's home, Dr. Power, in consultation with Dr. Webb, ascertained the following facts: The patient had been wounded by a 38-caliber bullet from a Smith & Wesson revolver, and the bullet had penetrated in the right second intercostal space about three inches from the right margin of the sternum. The bullet had ranged obliquely upward and backward, inclining slightly toward the right, evidently passing under the clavicle without fracturing the bone, and finally lodging under the skin at a point corresponding to the anterior border of the trapezius, midway between the mastoid and the acromion, where it could be felt distinctly by the touch. A large swelling had formed in the neck immediately after the injury. This was caused by large hematoma, which extended from the shoulder to the angle of the jaw laterally and from the second rib to the scapular region antero-posteriorly. All external bleeding had stopped and only a bloody ooze stained the dressings. The skin for some distance around the bullet wound was powder stained and burnt. The most notable sign that attracted the attention of the attending physician at this time—not more than two hours after the injury—was the "intense throbbing or pulsation which was perceptible in the swelling on the chest and neck, and a loud thrill, which could be felt along the course of the subclavian vessels, extending over the neck up to the angle of the jaw and down the shoulder and upper arm." The pulse in the arteries of the right arm was absent. It was also noticed that the arm on the opposite side was motionless and anesthetic all over the hand and forearm. Evidently there had been a coincident lesion of the brachial plexus.

The general condition of the patient had grown worse since his return home. Coincidentally with the development of the swelling and aneurysmal signs, he had become weaker; he now showed positive signs of shock and profound exhaustion; he was cadaverically pale and the skin was covered with a profuse perspiration. The pulse on the sound side was rapid and small. He had lost a considerable quantity of blood—sufficient to soak through his clothing—immediately after his injury, but this had ceased readily under slight pressure with the gauze pad applied by Dr. Power. It was evident, therefore, that this condition of progressive shock was due to the concealed bleeding in the hematoma. A compress was re-applied over the wound, and this again was covered with the ice bag. By midnight, four hours after the affray, the patient was so completely collapsed that he was believed to be moribund, and no hope was entertained of his recovery. He remained in this apparently dying condition until noon of the following day—September 4—sixteen hours after the injury, when the first signs of improvement were noticed and the patient began to rally. With this improvement the enormous swelling in the neck began to harden and contract, though the pulsation and thrill remained unchanged.

Dr. Power then states that the patient's temperature was above normal and fluctuated daily—September 4 to

8—from 100 in the morning to 103 in the evening. By absolute rest, diet, careful stimulation, and watchful nursing the patient continued to gain strength, though slowly. It was noticed, however, that the throbbing and thrill in the supraclavicular swelling continued to grow more diffuse and intense as the swelling diminished. No notable improvement was observed in the condition of the arm, which continued to be "of no use to the patient" and remained pulseless at the wrist and in the arm. This was M.'s condition when he was brought to the sanitarium in New Orleans, Sept. 8, 1900.

When I called to see him he was lying in bed, still extremely pale and exhausted from his long journey and the exertion involved in transportation from the train to the institution. His expression was anxious, and there was some complaint of pain in the neck. The right pulse, which had disappeared completely, was felt at the wrist very faintly to-day for the first time—the fifth day after the injury—showing some re-establishment of the collateral circulation. At 11:30 a. m., when the patient was admitted, his temperature was 98.8, but in the evening it rose to 101, with a pulse of 110 and respiration 22.

Upon examining the patient I first observed a dark circular slough, the size of a silver quarter, in the skin over the right second intercostal space, about three inches from the sternum. Numerous inflamed powder stains dotted the skin, testifying to the close proximity of the pistol when fired. The entire supraclavicular region is swollen, also the region of the trapezius, entirely obliterating the normal outlines of the clavicle; in the neck a space as large as the palm of the hand is bluish-black from extensive ecchymosis. The center of this spot is particularly dark and corresponds to the site of the bullet, which can be felt distinctly movable in a bed of semi-fluid hematoma. The skin of the entire supraclavicular region from the angle of the jaw to the shoulder on the right side is discolored from the deep subcutaneous extravasation. There is a very distinct subcutaneous heaving pulsation, this being most marked along the course of the subclavian vessels and the right internal jugular vein. This vessel swells and fills up the suprasternal space with each beat of the heart. The superficial veins of the neck and arm, the cephalic and basilic veins down to the elbow are all unusually prominent, and their dark-bluish color stands in conspicuous relief against the unusually pale, waxy skin. On palpation there is marked pitting on pressure from edema, over the clavicle and the entire supraclavicular region; the general pulsation seen over the supraclavicular region is distinctly confirmed by palpation. A widely diffused and intense purring thrill can be felt by the most superficial contact with the surface all over the neck, and more especially over the subclavian, jugular, cephalic, and basilic veins. The thrill appears to be transmitted in all directions from its point of greatest intensity, immediately above the middle third of the clavicle, all along the venous currents of the neck and arm as low down as the right hand. The most striking phenomenon is the peculiarly loud murmur which is heard all over the neck, chest, and arm, along the course of the venous trunks. This murmur is difficult to describe; it is a continuous hum, with diastolic whirring accentuations, and is heard with greatest intensity over the middle of the clavicle, and is harsh, buzzing, and, in fact, indescribable. Several odd comparisons were made by those who heard it, but no description or analogy appears to give an accurate idea of its extraordinary peculiarities. This murmur is so loud that it can be heard by listening attentively at a distance of nearly one inch

from the surface. This murmur, like the thrill, is propagated with greatest intensity along all the venous trunks from the bend of the elbow to the innominate veins and superior vena cava. It can be heard distinctly over the facial and temporal veins. Its vortex or loudest point is over an area the size of a silver dollar, situated just above the middle third of the clavicle, in the very center of the bullet tract, and evidently in a line with the subclavian vessels.

In spite of all this great vascular upheaval and disturbance, the work of repair was evidently progressing steadily in a favorable direction. The swelling of the original area had on the ninth day markedly subsided; the extravasation was being absorbed, and it was evident that the large stream of blood which was being poured out of the artery had found a direct outlet in the veins; these had accommodated themselves to the abnormal pressure, and were carrying off the overflow through comparatively safe channels back again into the circulation. Associated with these evidences of vascular disturbance there still remained a marked paresis of the entire right arm down to the fingers. The arm could be moved slightly by strong voluntary efforts, but pronation and supination were impossible, the arm usually remaining motionless, extended and passive by the side of the body, or it remained inert in which ever position it happened to be placed by the patient's left arm or by the hands of the attendants.

The sensibility was impaired all over the arm up to the shoulder, but sensation could be elicited by deep pricking with pins over the fingers and hand on the palmar and dorsal surfaces. The thermic sense was also greatly impaired, but the application of very hot water to the hand, as in washing this part, elicited some sensation on the part of the patient. The condition was really one of paresthesia and paresis rather than paralysis, and this encouraged the belief that the injury to the brachial plexus was a contusion and partial laceration rather than an actual division of its constituent trunks.

#### DIAGNOSIS.

By summarizing the evidence thus clearly presented the following points were determined: 1. That the course and direction taken by the bullet indicated that the missile had penetrated the neck by passing under the clavicle without injuring it, had crossed the path of the subclavian vessels just about where the scalenus anticus crosses the artery, and after injuring both artery and vein had grazed and contused the brachial plexus.

2. The immediate cessation of the radial pulse at the time of the injury, which continued to be imperceptible until the fifth day, and the coldness of the skin and pallid appearance of the arm, indicated that the circulation in the subclavian had been interrupted by the injury.

3. The positive and pathognomonic signs of arterio-venous aneurysm or varix, i. e., the continuous venous hum plus the rasping, buzzing double murmur heard with greatest intensity in the diastolic period—Broca and Wahl's signs, the intense vibratory purring thrill—*fremissement cataire*—propagated like a murmur at a great distance along the venous channels on the proximal and distal sides of the point of injury.

4. The spontaneous arrest of the bleeding shortly after the first primary hemorrhage, the absence of secondary bleeding, and, above all, the rapid subsidence of the hematoma while the intensity of the physical signs of aneurysm were increasing; the great fulness, pulsation, and distension of the cervical and brachial veins, more especially during the diastolic period—all clearly

pointed, in fact, demonstrated, that the subclavian artery and vein had been simultaneously injured by the bullet, the perforation leading to the almost immediate formation of an arterio-venous anastomosis.

It also appeared to be most probable that the anastomosis was a direct one, aneurysmal varix, and not through an intermediary sac, varicose aneurysm, though this point could not be positively determined at the time in consequence of the swelling above and under the clavicle in the neighborhood of the bullet tract. There was, however, no distinct globular or especially defined swelling. There was only a general hard swelling over the supraclavicular space filling the lateral aspect of the neck as with a mass of recent exudates and extravasated products, all masked by a dense, doughy edema of the skin. At first the entire supraclavicular region appeared to expand and pulsate as a whole, all over, with each beat of the heart; but latterly, as the swelling diminished, the pulsation was more defined and distributed most intensely along the veins embedded in the mass of exudates.

#### TREATMENT.

Having sufficiently disposed of the question of diagnosis, we were now ready to consider the more serious problem of treatment. What were the indications furnished by this remarkable and rare lesion? If we bear in mind the fact that the patient had come to us for treatment on the fifth day after injury, and was still suffering from the shock and anemia incident to the primary injury, and that the eschar existed, we will realize that we had reason to consider the possible dangers that menaced this patient from two points of view: 1, the possibility of secondary hemorrhage; 2, the remote dangers incident to the formation of a secondary or consecutive aneurysm of the artery proper, with all its attendant train of evils and dangers. As to the immediate dangers of possible infection and secondary hemorrhage, we were soon able to satisfy ourselves that they, at least, could be safely eliminated by a careful observation of the patient's condition during the first four days that followed his admission to the sanitarium.

From the moment that the patient was admitted to the institution the injured surface was subjected to the most careful antiseptic treatment and methodical compression with bandages and ice bags. The whole region was carefully washed with potash soap and lysol solution—1 per cent.—followed by alcohol. Wet antiseptic compresses were applied, and the whole supraclavicular region and lateral surfaces of the neck were subjected to vigorous compression with a spica bandage, over which an elastic woven bandage was adjusted, and over this a large ice bag was applied. This firm elastic compression, with the addition of cold, promoted the absorption of exudates and extravasated products, and we hoped also that it would help to moderate the violence of the strain that was being constantly forced upon the veins through the aneurysmal orifice. With these simple measures, aided by absolute rest, a light nutritious dietary, consisting chiefly of milk, fruit, broths, and cereals, and other hygienic measures, the robust nature of the patient soon asserted itself. The temperature, which upon admission had oscillated between 101 and 102 F., gradually subsided, so that by the fourth day—ninth after injury—it rose no higher than 99. The pulse likewise moderated in frequency, and fell to 84-90. The discoloration of the surface rapidly diminished, the dark bluish-black area of extravasation being limited to the spot occupied by the bullet. The eschar at the wound of entrance fell off Sep-

tember 11—eighth day after injury—leaving behind a healthy, granulating surface. The pain and superficial tenderness over the neck and chest diminished daily; the edema, which had completely obliterated the clavicle and all the surface anatomy of the region, now subsided, and the clavicle was easily outlined under the thin skin. It was evident from all these signs of improvement that the danger of infection which we had first apprehended from the fever, the pain and the tenderness over the parts, could now be definitely eliminated. And as there was no oozing at the point of entrance or other warnings of secondary bleeding, I now felt encouraged to believe that this grave source of apprehension would also soon be eliminated. On the other hand, the physical signs of the aneurysm became, if anything, more pronounced as the edema of the skin subsided. The hum, murmur, and thrill became more noisy and turbulent, and could be studied to still greater advantage as the vessels approached the surface. The swelling and turgidity of the jugular and brachial veins also became more perceptible. The pulsation in the internal jugular was most striking. With every beat of the heart this vessel pulsated so forcibly and became so distended that it filled the entire suprasternal and pretracheal space, thus demonstrating that while the venous system had accommodated itself to the new conditions, and was standing the great strain imposed upon it by the sudden shunting or shortcircuiting of the arterial current, the conclusion was unavoidable that a condition of permanent overdistension and engorgement was laying the foundation for future evil. The paralysis of the arm still continued; there was a slight improvement in the movements of the arm, and the sensibility of the skin was more acute, but apart from this the arm remained lifeless and inert by the patient's side.

For the moment all fear of immediate complications could be dismissed, though we realized that fully three weeks after healing would have to elapse before we could safely state that the danger of secondary hemorrhage could be entirely eliminated.<sup>2</sup> As the patient resided in an isolated settlement in the country, and could not remain long under our observation, the question that arose was, "Should the patient be allowed to return home, with instructions to return again for further treatment in the event that other serious developments should follow: or was it the wiser plan to anticipate the complications and dangers that the future might have in store for him, by advising an early and radical operation that would rid him of this dangerous lesion under the most favorable conditions of surgical preparation?"

While the question involved many debatable propositions, which will be more appropriately discussed in another section of this contribution, I will state that in view of the progressive improvement in the general condition of the patient, and the probability that he would escape the dangers of secondary hemorrhage and other immediate complications, I had concluded, in accordance with the classic recommendations on the subject, that I would abstain from all operative intervention, and would allow the patient to return home after the wound had healed completely. Had I known the exact anatomic relations of the aneurysmal orifice, which were only determined at the time of the operation, I would have made a special trial of systematic digital compression over the anterior scalene after all the acute reactionary swelling had subsided. But even with the favorable position of the anastomotic orifice, which was immedi-

ately in the lowest center of the scalene tendon, it is very doubtful that this mode of treatment would have succeeded, as the clavicle was directly in the way of effective compression; furthermore, in the cases in which this method had been tried it had failed altogether, and I therefore gave it little consideration. On the other hand, the patient, who had been profoundly impressed with the gravity of his injury, reminded me insistently that he would not be able to remain in the city for observation, or to return again at some future time if complications should arise, without a great sacrifice—a greater sacrifice than his limited resources would allow. He was anxious to have something done that would be decisive and that would relieve him permanently of the worry and uncertainty of a lesion which he might tolerate in time, but would always remain a menace to his comfort and even to his life.

The dangers of a radical operation and the unusual character of such an operation were fully explained to him, but he preferred to take his chances, provided there was a reasonable prospect of recovery and permanent cure.

The determined attitude of the patient, who showed himself as fearless as he was determined, coupled with my serious misgivings as to the final outcome of the case if allowed to drift along its natural course, led me, in spite of my doubt as to the wisdom of this decision, to acquiesce to the patient's courageous appeal and to give him the benefit of the operation.

Without underestimating the difficulties that were to be encountered, I still believed that by adopting a carefully prepared and matured plan of action I would be able to overcome the chief obstacles in the way of a safe dissection of the varix and complete control of its anastomotic orifice. The main objects of the operation that were kept in view were: 1. To obtain free and easy access to the entire injured area by preliminary osteoplastic section of the clavicle from its outer third to the sternoclavicular joint, which was to be disarticulated or temporarily excised. 2. To obtain complete provisional control of the subclavian circulation by applying a temporary traction-loop upon the first portion of the subclavian or innominate artery, which by lifting the vessel from its bed would occlude the main trunk and its most important collateral branch, the vertebral. 3. To completely explore by careful dissection the point of anastomotic communication existing between the subclavian artery and vein. 4. To permanently control the subclavian artery over the distal and proximal side of the anastomosis by ligature. 5. To provisionally clamp or ligate the vein above and below the venous orifice as a preliminary to the extirpation of an intervening sac that might exist between the vessels. 6. Then, if possible, to suture the venous orifice by lateral phleborrhaphy, thus allowing the venous circuit of the upper extremity to be re-established after the removal of the temporary clamps or ligatures on the vein. 7. To restore the parts to their normal condition by wiring the divided clavicle into position. Incidentally, and as a minor feature of the operation, the bullet would be extracted.

That this desirable but difficult program would be carried out in all its details I did not fully anticipate, but I did expect to accomplish the main purpose of the operation if I once succeeded in obtaining a complete control of the innominate, and obtained a free and open field for the manipulations necessary to dissect the anastomosis. As the sequel and details of the operation show, unexpected anomalies in the arterial distribution and the freedom of the collateral supply did come near

2. See Will's case, secondary hemorrhage after healing of wound, causing death three weeks after injury.

upsetting my plans and added greatly to the perils of the patient. Nevertheless, the value of a carefully planned operation and thorough preparation for emergencies was certainly well illustrated in this case, and while it may remain a debatable question whether a procedure of this kind is justifiable in just such conditions as those described in this case, it can not be denied that the final result obtained, even at the price of a mutilation of the paralyzed hand and arm, is far more satisfactory—considering the occupation and specially unfavorable conditions under which this patient was placed—than the uncertainty of leaving this grave lesion without interference to the care of nature alone.

(To be continued.)

## Clinical Report.

### CASE OF ACUTE PANCREATITIS WITH FAT NECROSIS—OPERATION—RECOVERY.

WILLIAM J. MAYO, A.M., M.D.

SURGEON TO ST. MARY'S HOSPITAL.  
ROCHESTER, MINN.

J. C., male, aged 59, American, was admitted to St. Mary's Hospital on June 11, 1901, with the following history:

For two years he had suffered from attacks of indigestion and at times had refrained from eating for twenty-four hours or more to obtain relief. While able to attend to his professional duties during this time, he lost 25 pounds in weight.

On June 4, was suddenly seized with agonizing pain in the epigastrium, accompanied by marked symptoms of collapse, requiring anodynes and vigorous stimulation. Vomiting and retching were frequent. The abdomen became greatly distended and symptoms of acute obstruction of the bowels developed. June 5 and 6 the condition remained about the same, temperature ranging from 100 to 102, pulse from 96 to 120. Hiccough became most distressing.

The bowels acted slightly as a result of purgation and enemata but without relief to the abdominal distention. Beginning on June 6, the stomach was washed out and rectal feeding instituted with some relief to the acuteness of the symptoms, although the main features were practically unchanged. On this date an indefinite tumor of irregular outline could be detected under the right rectus above the umbilicus, in the region of the gall-bladder. On June 7 and 8 his condition was practically unchanged, the hiccough and extreme nervous unrest being most marked.

The physical examination on admission to the hospital revealed the following:

A large, heavy man, of splendid physique, vital organs in good condition excepting for a trace of albumin in the urine. The abdomen was very tympanitic: To the right of the umbilicus and above it was an irregular, indefinite mass, apparently the size of a large fist. The temperature was 101 to 102; pulse 120, and of poor quality. Patient was very restless, hiccoughing at intervals, and having every appearance of extreme illness. There was slight jaundice. The diagnosis was gangrenous cholecystitis with probable perforation. Patient was operated on at once. The abdomen was opened through the right upper rectus, coming directly upon a greatly thickened and adherent omentum, which was infiltrated with little white or brownish spots from the size of a hempseed to that of a pea or larger. On loosening the adhesions some bloody fluid escaped from the peritoneal cavity. It was now noticed that the mesentery was infiltrated in a similar manner. The peritoneum, while reddened, was unaffected. The diagnosis of fat necrosis was evident.

Raising the omentum and transverse colon, the greatly enlarged pancreas could be felt like a pudding in a tight sac. With a small aspirating needle this was aspirated in several places, withdrawing only bloody fluid. The rectus was severed laterally and a search instituted for the gall-bladder, which

was found far to the right and wholly unconnected with the tumor previously detected. The gall-bladder was greatly thickened and contained one enormous stone, the size of a small hen egg. There was also some muco-purulent material in the gall-bladder. The stone was removed and a large rubber drain inserted and sutured to the opening in the gall-bladder with a catgut suture in purse-string fashion, drawn tightly to prevent leakage. The drain was brought out of a stab wound in the right groin. A large wick of gauze was placed along with the tube into the right kidney pouch. The whole of the anterior wound was closed. Time of operation was 45 minutes.

The patient was placed in bed in extreme shock, with restlessness, muscle twitching, cold perspiration, etc. Temporary delirium developed after the anesthesia had passed away. Atropin, as advised by Crile, in this form of shock, was found most efficacious. Strychnia, rectal exhibition of saline solutions, etc., were also resorted to. At the end of 18 hours an immense drainage through the rubber gall-bladder drain commenced. It was a bloody, serous fluid with little evidence of bile. This discharge was very irritating and on examination showed pancreatic fluid and bile. The quantity was so great as to saturate a large dressing every four hours. In two weeks this irritating discharge was gradually replaced by bile of a more normal appearance, and at the end of four weeks the fistula closed. The patient, while in a most critical condition for a week, slowly regained his health, leaving the hospital in seven weeks, and he is now in perfect health, up to his usual weight, and can eat and digest normally.

It is evident in this case that the gallstone had been the cause of a cholangitis which extended to the pancreatic ducts, with resultant acute pancreatitis and fat necrosis. The free drainage and relief of tension following the opening of the gall-bladder checked the process short of abscess formation.

The fine constitution and previous exemplary habits of the patient were great factors in the recovery.

## New Instrument.

### AN ANTISEPTIC THERMOMETER.

There is no doubt but that bacteria can be transmitted by the ordinary clinical thermometer, and extreme and continued care is necessary to prevent this. Ordinary washing and wiping will not suffice. The Norwich Pharmacal Co. has just

gotten out an antiseptic thermometer case which seems to meet all requirements. It is simply a glass-tube holder in which can be kept antiseptic solution without leakage and into which is screwed the thermometer as in ordinary holders. The increase in size of this over ordinary holders is so slight as to make it scarcely noticeable in the vest pocket.

**War on Rats.**—The cities in which the plague has made a brief appearance and then subsided, all made war upon rats as an indispensable measure. The *Brazil-Medico* is inclined to attribute the recurrence of plague at Rio Janeiro to the neglect of this measure, which was considered superfluous by the authorities. The recrudescence of the disease and the appointment of a new head of the health office has been followed by stringent measures against rats. A premium is to be paid for dead rats, and for rat dogs of a good breed, which will be bought by the municipality and distributed. Phosphorus paste is supplied on an extensive scale to the police to poison rats in sewers, docks, etc. To prevent the importing of rats to obtain the premium, the source whence the carcasses were derived must be proved.

SATURDAY, JANUARY 11, 1902.

## NATIONAL BOARD OF MEDICAL EXAMINERS.

The necessity of devising some method for overcoming the present anomalous conditions regarding the regulation of the practice of medicine in the various states becomes more evident each year. According to the analysis of the state medical laws published in *THE JOURNAL* for November 16, last, there were then thirty-seven states which required examinations. Last November, Rhode Island adopted a new law requiring an examination, so that to-day there are thirty-eight states and territories which demand that hereafter all must pass an examination before being admitted to practice. Besides these there are nine states in which an examination or a diploma is required and the number of colleges recognized by some of these states is quite limited.

The conditions thus created make it a serious matter for the physician who desires to remove to another state to practice; for, the best of men, after a few years, find themselves very deficient in at least some of the branches in which they would be compelled to be examined. The young graduate, while yet well up in all the fundamental branches, desires to go through the ordeal of passing all the examinations necessary to entitle him to practice in any part of his own country. But he finds this is impossible. Hence, he selects his field, conforms to its laws, enters on his life work, and soon finds himself with the great majority—rusty in many of the branches and almost compelled to stay where he is. A remedy has been suggested in reciprocity. A few of the states have already grouped together for mutual exchange of courtesies, but reciprocity will never be universal among all the states, at least not until there is a much more uniformity in legislation than now prevails or that is likely to prevail for some years. But even a uniformity of laws will not suffice; there must be a uniformity in tests and standard, which will never come because of the multiplicity of boards of examiners, the majority of which are created by political influence and not by the selection of men qualified for the positions of examiners in scientific medicine.

In place of reciprocity it has been suggested on different occasions that there be created a national board of examiners which shall have authority to grant licenses which shall be recognized throughout the country. The constitution, however, does not place the regulation of the practice of medicine among the functions of the government in various parts of the country at definitely fixed

eral government, and consequently the practical carrying out of the idea of a national board is met by obstacles not easily overcome, provided the idea is to compel the recognition of certificates from such a board by the various states. The constitutional objections would not apply to such a board as we suggest below. At least, the obstacles are no greater here than in carrying out the idea of reciprocity, so-called. In either case there must be a voluntary relinquishment of rights on the part of the state, and the state can only give its examining or licensing boards the privilege of accepting the credentials of a corresponding board of another state. Without taking space to give our reasons, we believe the ultimate results of reciprocity, as now understood, would be to lower rather than to elevate the standard.

A national board of examiners is the most practical solution of the difficulties before us, and if we were to offer a suggestion it would be that such a board should be analogous to that proposed by Dr. Roddick for the dominion qualifications in Canada where they have the same constitutional difficulties to meet as we have here, although their provinces are very limited in number compared with our states and territories.

At the present time there are three Government services, to enter which it is necessary that the applicant pass an examination. These examinations are at present held by the respective services—the Army, the Navy and the Marine-Hospital. In place of these let there be created a national board of examiners, whose certificates of qualification shall be a prerequisite to candidacy for any medical position under the Government. While ostensibly this board would be created to examine those desiring to enter the medical service of the Government, practically the acknowledged object would be the creation of a body to examine applicants and to grant certificates or diplomas which should be a guarantee of a thorough and practical medical education. In number the board should consist of not less than five or more than nine: its members should receive a good salary and devote all their time to the work, the expenses to be met by the fees of applicants. The appointments on this board might be made by the President on the recommendations of the heads of the medical department of the Army, the Navy, and the Marine-Hospital Service. It is presumed that men would be selected who would be well qualified to represent the different branches of scientific medicine—physiology, pathology, chemistry, anatomy, surgery, obstetrics, etc. The examinations should in part be conducted in hospitals and laboratories so that practical and not theoretical knowledge would be demanded. No school or system of practice should be recognized, but the examination should cover all the essentials; it should be thorough and complete, and sufficiently rigid to satisfy the demands of the most exacting of the states at the present time. It is presumed that a fair standard of preliminary education will be required, as well as a degree from a reputable medical college. The board should

times, so that no great sacrifice would be necessary on the part of those who desired to take the examination. A further practical examination might be required of those entering the Government services, but the general qualifications given by the board should be also a prerequisite for any medical employment under the government, including pension boards, etc.

If such a board were created and it required thorough qualifications before one could pass its examination, which is taken for granted, it would not be long before all the states would be willing to recognize its certificate. It would place before the ambitious in our profession a chance to get a diploma that would be an honor to its possessor and that would be registrable in every state in the Union. The state boards might still exist and act for those who cared only for a state license, but any one legally possessing a United States certificate from this national board would not have to submit to a state examination on every change of residence.

We believe that this is a practical remedy for the conditions now before us, and it is offered for the consideration of our readers.

---

#### AMERICAN SOCIETY OF NATURALISTS AND AFFILIATED SOCIETIES.

The twentieth annual meeting of the American Society of Naturalists was held at the University of Chicago December 31, 1901, and January 1, 1902, and the occasion proved to be a noteworthy one in many respects. The holding of an annual meeting in Chicago, "so far west," was regarded at first as a rather uncertain experiment, but the number in attendance and the quality of the material presented showed very clearly that Chicago, for various reasons, is far from being an unfavorable place for meetings of even the most purely scientific character.

The lecture by L. O. Howard of the Department of Agriculture on "International Work with Beneficial Insects," was a good illustration of the economic value of scientific methods applied to the study of destructive parasitic diseases of various trees and plants. The annual discussion had for its subject "The Relation of the American Society of Naturalists to Other Scientific Societies." It appears that the American Association for the Advancement of Science, also a strong organization, intends to abandon its summer meetings and that a year from now there will be a large meeting of many societies in Washington. The co-relation of the various societies, the formation of central and regional societies, and the holding of general and more local meetings—in short, the most effective organization of the purely scientific societies of the country—were considered. The problem seems not at all unlike that confronting the medical profession of the United States as it seeks to advance the interests of science by means of the many societies and associations that have been formed from time to time, often without careful consideration of the evident value

of centralization, affiliation and union. The annual address by Professor Sedgwick of the Massachusetts Institute of Technology on "The Modern Subjection of Science and Education to Propaganda" was of direct bearing upon medicine. Indeed, his strongest illustrations were the propagandas carried on by the anti-vivisectionists and by the advocates of instruction in "temperance-physiology" in the common schools of this country. It will probably be a matter of considerable surprise to many readers of *THE JOURNAL* to learn that the instruction in physiology in the common schools of most of our states is completely subjected to propagandism of the most virulent and uncompromising character. Surely this is not a safe principle to follow in education.

Among the affiliated societies, the meetings of the Association of American Anatomists, of the American Physiological Society, and of the Society of American Bacteriologists are of direct interest from the medical point of view. The meetings of these three societies were among the most successful of any so far in their history. Brief references may be permitted to some of the many papers presented before the Physiologists and Bacteriologists. Mendel and Rettger brought forward certain observations that indicate an important relationship between the spleen and the pancreas, because an extract of the spleen when added to an extract of the pancreas greatly increases the proteolytic powers of the latter. Loeb and Lewis found that unfertilized sea urchin eggs left undisturbed in sea water for a few hours become insusceptible to fertilization, but if kept in a mixture of sea water and potassium cyanid, the latter having been allowed to evaporate, the eggs may be fertilized after seven days, the potassic cyanid apparently inhibiting certain fermentative processes in the eggs that are of a distinct mortiferous nature. Loeb also advanced an electrodynamic explanation of life phenomena to take the place of the thermodynamic explanation heretofore in vogue. Pure sodium chlorid solution of the same osmotic pressure as sea water is toxic for the fertilized eggs of *Fundulus*, a marine fish, the toxic effect being due to the negatively charged Cl ions, which may be neutralized by small amounts of positively charged bivalent and trivalent metal ions. Mathews showed that the effect of a salt upon nerves is dependent upon the electrical charges carried by the anions of the salts. Important deductions were made in regard to the nature of nerve impulse, electrotonus, and other electric phenomena. These experiments, which may be just hinted at for the present, show again the essential rôle played by chemico-physical factors in life phenomena.

In the Society of Bacteriologists, whose deliberations were guided by Professor Welch of Baltimore, many noteworthy investigations were presented: Novy's observations on the germicidal actions of certain organic peroxids are important because of their probable therapeutic significance. It seems that certain organic peroxids have been studied whose germicidal action is exceedingly powerful but which are harmless to human

beings and similar animals—apparently just the thing wanted for the successful treatment of many infections of the intestinal tract and elsewhere. In a supplementary note on the etiology of yellow fever presented by Dr. Carroll of the Army Medical Hospital, Washington, it was shown that the virus or cause of yellow fever, contained in the blood of yellow fever patients as demonstrated by the experimental inoculations of Reed, Carroll and Agramonte, is so small that it passes through porcelain filters. Hence it would seem to belong to the group of pathogenic agents that investigators believe are so infinitesimally small that it is hopeless to expect to find them in the sense of ocular demonstration by means of our present methods. A number of other interesting and valuable observations along bacteriologic lines, both from the standpoint of pathology as well as pure or applied bacteriology, were presented, the program being filled to the limits. Suffice it to say that the proceedings of the societies referred to indicate a gratifying activity in research in the various branches represented.

---

#### THE MEMORIAL INSTITUTE FOR INFECTIOUS DISEASES.

As noted in another column of the present issue, Mr. and Mrs. Harold F. McCormick, of Chicago, have given a considerable sum of money for the establishment of an institution for the investigation and the treatment of infectious diseases. We made an announcement of this gift some weeks ago, but at that time we were not permitted to give the name of the family, or any of the particulars. The terms of the gift confine the immediate activities of the institution to scarlet fever and allied problems. A board of trustees, the majority of whom are medical men, has been appointed, an organization effected, and the preparations are under way for the carrying on of work in rented quarters. Professor Hektoen has been selected director, and this is a guarantee that the work done at the Institute will be of the highest order and of scientific worth.

In connection with the investigation into the causes and nature of scarlet fever and other similar infectious diseases, provisions are being made for the treatment in hospital of a small number of patients. All indications point strongly to the permanent establishment before long of an institute for infectious diseases in which original investigation and clinical work will go hand in hand, the one completing and aiding the other. It is hoped, of course, that arrangements may be made also for the clinical instruction of students of medicine in the acute infectious diseases of children, a desideratum that surely may be fulfilled without in any way interfering with the main purpose of the institute. The name selected, namely, "The Memorial Institute for Infectious Diseases," indicates at once the nature of some of the motives that lead to the undertaking and also the intention of the founders to secure for it permanency and comprehensiveness.

The general object of the Institute is one that appeals to philanthropist and scientist alike. No better selection of location than Chicago could have been made. We believe that this is one of the first, if not the very first, substantial and direct gift of money to scientific medicine in Chicago. It is true that much money has been given to hospitals and similar institutions in Chicago, but we recall no considerable donation before this for the direct advancement of scientific investigation. Herein lies a noteworthy significance because the McCormick donation is another welcome instance of the direct interest that private wealth is beginning to take in the purely scientific side of medicine. Less than a year ago Mr. Rockefeller gave a large sum for medical research in various centers of this country, and the recently incorporated "Carnegie Institution" of Washington, with an endowment of \$10,000,000, aims also at the furtherance of scientific investigation in medicine as well as in other branches of knowledge. The opportunities for the medical investigator in this country has consequently increased manifold within a few months—a most encouraging and stimulating fact for all those that are interested in the scientific development of American medicine.

---

#### OPERATIVE TREATMENT FOR CHRONIC NEPHRITIS.

With the evolution and growth of antisepsis and asepsis, the last quarter of a century has witnessed a remarkable expansion of the field of operative surgery. The insidious transition from structural to organic disease has forced the clinician, in many instances, to invoke the early counsel, if not the operative aid of the surgeon. The former has learned that certain affections considered strictly medical have also a distinctly surgical aspect, and that if he wishes to render his patient the best service, he must be prepared for contingencies that, while they may never arise, will in the event of their development, require speedy and skilful surgical treatment. Therefore, the clinician must early have the surgeon share with him a knowledge of the details of the case, so that both may occupy common ground and be able promptly to reach an agreement as to the procedure to be followed in accordance with the conditions that may be present. It is, for these reasons, that the plan adopted by two physicians of the Pennsylvania Hospital—a clinician and a surgeon—of delivering joint clinical lectures on subjects that can profitably be treated from the viewpoint of each is to be commended.

The division of labor in medical practice resulting from the evolution of specialism and due to the enormous growth and progress of medical science makes it scarcely possible for the practitioner to be expert both as clinician and as surgeon. There are, however, many conditions that at different stages demand the services of both. It will not be necessary to do more than merely advert to some of these, such as appendicitis, abscess

or gangrene of the lung, visceral malignant disease, hemorrhage secondary to gastric or intestinal ulceration, perforation of the stomach or bowel, abscess or new growth of the brain, liver or spleen, cirrhosis of the liver, and so on. To this list of diseases, essentially medical primarily, but in the treatment of which the services of the surgeon are not rarely required, Dr. George M. Edebohl<sup>1</sup> now adds chronic nephritis. The proposition to treat this affection by operative measures is based not alone upon theoretical considerations, but also upon an experience already comprising some eighteen cases. The suggestion for such a procedure emanated from the successful results in several cases of chronic nephritis in which nephropexy was performed for the purpose of anchoring a movable kidney. Albumin and tube casts disappeared from the urine, and the patients were restored to health. By reason of this experience, Dr. Edebohl resolved to apply surgical treatment to all cases of chronic nephritis that should come under his observation. The operation consists in exposure of the kidney through the loin, with excision of its proper capsule. All of the patients thus treated are reported to have done well. The good results obtained in these cases are attributed to the development of numerous large blood vessels, particularly arteries, that develop in the strong connective-tissue adhesions that formed between the kidneys and the surrounding tissues, the blood stream passing from the latter to the kidneys. This, it is thought, leads to gradual absorption of the interstitial or intertubular inflammatory products and exudates, thus freeing the tubules and glomeruli from compression, constriction and distortion, and permitting the re-establishment of a normal circulation, with the regenerative production of new epithelium capable of carrying on the secretory function.

The proposition here thus briefly outlined is certainly a most startling one, and it is not likely to meet at once with general acceptance; but any theoretic objections to its practical application must disappear in the face of successful results in actual experience. Of course, the operation would not be undertaken in the presence of any incurable complication or any condition forbidding the administration of an anesthetic, nor should it be undertaken unless the probable expectation of life is more than a month, inasmuch as the beneficial effects are not manifested in a much shorter time.

#### HEMATOGENOUS TUBERCULOSIS.

It is a well-known fact that tuberculosis of the lungs involves by preference the apices, but no explanation that has been offered is entirely satisfactory. Deficient functional activity of the portions of lung in question would seem to be in general an adequate predisposing factor. This does not necessarily imply, however, that infection takes place invariably by way of the air passages. As opposed to the view that the air is exclusively the medium through which tubercle bacilli gain access

to the apices of the lung, is the report by Baumgarten<sup>1</sup> of experimental observations in which injections, in not too large amount, of virulent tubercle bacilli into the uninjured urethra and bladder were followed by tuberculosis of the apices of the lungs. The same result followed subcutaneous and intraocular inoculation. When large amounts of bacilli, however, are employed, or when intravenous inoculation is practiced, miliary tuberculosis is likely to result. Under these circumstances, also, the special localization of the morbid process must be attributed to the deficient functional activity of the apices, with which sluggishness of the circulation goes hand in hand, whereby tubercle bacilli contained in the blood are more readily deposited.

#### THE PROPOSED UNITED STATES HEALTH SERVICE.

The bill that has been introduced into both houses of Congress providing for a National United States Health Service, on the basis of the present Marine-Hospital Service, and practically a continuation of the same under another name with wider functions and responsibilities, is one that deserves the careful consideration of our profession. Two facts are self-evident. One is that the present scope of the Marine-Hospital Service is far more extensive than that originally intended and that it is under present conditions constantly extending to meet the demands. The other is that while we need a public health service the still existing present limitations of the Marine-Hospital Service under its original organization are a serious hindrance to its fully meeting the country's needs. Whether what is practically a simple change of style and title will do this, may possibly be a question open to argument and it is to be hoped it will receive due consideration. The Marine-Hospital Service includes a body of trained sanitary workers whose skill and experience would be invaluable and could hardly be dispensed with, but this does not preclude the possibility that a certain amount of reorganization would be advisable if we expect to have at once the best results. It may be that it would, but it is a question worthy of the consideration of the profession. What is needed and wanted is the best that can be had, in view of the very important functions of a national health department, and nothing short of this will be satisfactory. We must not too slightly disregard some of the already expressed ideals of the profession as to a national board of health and which are to all appearance at least hardly embodied in the proposed legislation. These may not be all attainable, but we should secure what we can, and make certain that the proposed body is such as to command the sympathy and cordial support of those who alone can make it truly effective. We publish elsewhere the text of the bill for the careful consideration of our readers.

#### SPLENIC ANEMIA WITH ASCITES.

Since the systematic description by Banti in 1894 of a symptom-complex comprising enlargement of the spleen, associated with anemia, and later the development of ascites, the name Banti's disease has been applied to this disorder. Three stages in the progress of

1. Medical Record, Dec. 21, 1901, p. 961.

1. Wiener Med. Woch., Nov. 2, 1901, p. 2049.

the affection are distinguished: 1. an anemic stage, characterized by enlargement of the spleen and anemia, and lasting from three or four to ten or eleven years; 2, a transitional stage, of uncertain duration; and 3, an ascitic stage, which usually terminates fatally in from six months to a year. In Banti's opinion, the spleen is the primary seat of the disease, toxic substances being generated in it as a result of some hypothetic infectious process, entering the circulation and causing anemia, and, by passing through the liver, causing hyperplasia of the interstitial connective tissue. It has, further, been suggested that the toxic substances may be derived from the gastro-intestinal tract, reaching the spleen through the circulation. The question has been raised whether cases of so-called splenic anemia or lienal pseudoleukemia with ascites and little or no cirrhosis of the liver do not also represent a variety of Banti's disease. Various influences have been made responsible for the ascites, such as cirrhosis of the liver, stasis due to enlargement of the spleen, anemia, lymphatic obstruction from enlargement of mesenteric and retroperitoneal glands; but the question must still be considered as undecided. One of the features of the disease to which little attention has hitherto been given is a tendency to hemorrhage; thus, epistaxis, hematemesis, hemoptysis, hematuria, and other forms of hemorrhage have been noticed. The skin is generally pale, although occasionally it is pigmented. The urine may exhibit little or no change, and slight fever may at times be present. In the blood, at least in the later stages, there is a deficiency in the red and white corpuscles, and in the hemoglobin. The alkalinity of the blood has also been found increased. In diagnosis, the most important consideration is the presence of chronic enlargement of the spleen not due to ordinary causes. The condition under discussion differs from spleno-medullary leukemia in the absence of hyperleukocytosis; from lienal pseudoleukemia, in the absence of a disproportionate increase in the number of lymphocytes; and in the presence of leukopenia. In treatment, splenectomy has been recommended and practiced successfully in a number of cases. Among drugs arsenic, iron and iodine have been employed.

#### THE BIBLIOGRAPHIA MEDICA.

The publishers of the *Bibliographia Medica*, the European successor to the *Index Medicus*, have issued a circular in which they state that unless they obtained 250 subscribers before December 31 last, at the newly raised annual subscription price of \$24, they will have to suspend its publication. It would seem that there ought to be at least 250 who are sufficiently interested to pay the price, to say nothing of the public libraries to which it is so valuable. We have to remember, however, that this is only history repeating itself: the *Index Medicus* in its last years went through the same experience. The fact appears to be that medical literature is increasing and that the difficulty and expense of collecting and publishing its bibliography have correspondingly increased, while the number of those calling for it in its completeness is not enlarged in proportion. If the *Bibliographia Medica* goes under, as there seems to be reason to fear,

we may conclude that what is demanded is not such a comprehensive all-exhausting bibliography, but rather a more limited and discriminating one. Much of the medical literature of the day, as indeed of all time, is ephemeral, and its preservation is, in itself, not a matter of importance. Much of it contains nothing new; some of what is novel is only error, and a great deal too much consists in duplication, triplication and still further multiplication of the repetitions of the same facts. There are authors who seem to think that reiteration is the only way to put their work before the profession and they do this so extensively and effectively that an astonishingly large amount of print is spread over a very limited modicum of fact. Sometimes the authors publish their articles unaltered in as many different publications as will receive them; sometimes they paraphrase them slightly or extensively, but make them cover the same facts. Some have a faculty of making a small amount of material go a long way and there are medical writers whose articles can not safely be briefed in summaries of current literature for this reason. When a subject becomes popular, so to speak, like appendicitis or tuberculosis at the present time, the amount of literature produced is appalling and the culling out of what is of value in it is itself a tremendous task. There is no medical or surgical subject of importance that has not its bibliography thus encumbered with a mass of papers which, while not always without an ephemeral utility as stimulants of discussion in medical societies, etc., have no lasting value and could well be spared from the literature. Their enumeration only confuses the investigator and wastes his time and energies in useless bookwork to his disadvantage. It will be a misfortune if the *Bibliographia Medica* is discontinued and if, as it appears may be the case, such publications can not succeed, let us hope that a less expensive and more discriminating one will have a better reception. Even if the *Bibliographia Medica* should cease its publication there would still be many resources for the student of medical literature remaining. What is being done in this country is well known, but it is of interest to note that similar plans of keeping up the record of local or national as well as general medical literature are being carried out abroad. The *Revista Med. del Uruguay* has undertaken the task of publishing an index of original articles appearing in its South American exchanges. The *Rousski Vrach* is doing the same for Russia. The *Deutsche* and the *Muenchener* medical weeklies review a large part of the contemporaneous field in Germany, and certain journals are accomplishing the same in their specialties for France. None of them, however, have appeared so far to even aim at the completeness with which current literature has been indexed in *THE JOURNAL* for the past two years. The usefulness of the German "Jahrbücher" has long been appreciated and with all the means at his command the medical worker of the present day has altogether unprecedented facilities.

---

**Women Physicians Receive Appointments.**—Miss Steinberger, M.D., has been appointed assistant in the gynecological clinic of the Budapest University, and Miss Kurtucz, M.D., demonstrator at the Institute of Physiology.

## The Organization of the Medical Profession.

### I.

#### A Statement of Facts.

The Committee on Reorganization, appointed by the American Medical Association in 1900, which reported at the 1901 meeting of the Association at St. Paul, when preparing its report attempted to gather statistics concerning medical organization, and especially as regards the number of those who belong to medical societies. Reports were received from every state, although from some the results as to accuracy were not very satisfactory, it being impossible in some of the states to more than guess at the facts regarding the number belonging to medical societies. However, basing its conclusions on more or less reliable information, the Committee concluded that the total membership of the medical societies at that time was approximately between 34,000 and 35,000.

In arriving at these figures no attempt was made to take into account those who belong to more than one society, although in some instances one individual might belong to half a dozen or more organizations. Neither was there any allowance made for those who were only nominally members, such as those who neither attended the meetings nor kept up their dues—in other words, delinquent members and those who, according to the constitution and by-laws of the various societies, should not be classed as active members. Taking into account all these and other things, it was concluded that a fair statement to make was that not more than 33,000 physicians in this country belonged to medical societies.

The number of regular physicians in the United States is unknown. Various reports are published, these varying in number from 100,000 to 120,000. Probably the mean of these, 110,000, would be practically correct. This gives us the startling fact that **there are 77,000 physicians in the United States who do not belong to any medical society whatever.**

Those who know the value of medical societies must acknowledge that the revelation is an appalling one. It is a revelation that accounts for the wretched condition that our profession is in as a body politic and as a social factor in many ways. It is jealous, antagonistic, discordant, disorganized, powerless, without unanimity of thought or action on important questions—ethical, social or scientific—without influence socially, politically, or in any other way.

What is the cause of these conditions? Why is it that not one in three physicians belong to a medical society? Does the fault lie entirely with the two-thirds, or is it a fact that for some reason our medical societies are not such as to make membership in them both available and valuable? Can existing societies better perform the functions for which they are created and be made more available for those for whom they are intended? These are important questions and well worthy of thoughtful consideration.

It is quite probable that those who have given thought to the subject would, without hesitation, say that several things contribute to the existing conditions as regards organization. The first rests with those who are

not members. These are apathetic, indifferent or ignorant of the practical value of membership in medical societies.

The second is the want of medical societies in many localities so that those who desire to become members can have the opportunity.

The third rests with the societies themselves. These are not performing their full functions as organizations representing the medical body politic; as educational or scientific bodies the majority of them are not conducted for the best interests of all their members.

Accepting these propositions as true, the remedy then will be: 1. to arouse those not now members from their apathy and indifference and convince them of the value of membership; 2. to organize and encourage medical societies in every part of the country, and 3. to stimulate existing societies to more active work and, if necessary, to adopt different methods.

Possibly a consideration of the subject of organization of the profession will not be out of place in this journal, which is the mouthpiece of the great National organization of medical men whose avowed objects and principles are:

"To federate into one compact organization the medical profession of the United States, for the purpose of fostering the growth and diffusion of medical knowledge, of promoting friendly intercourse among American physicians, of safeguarding the material interests of the medical profession, of elevating the standard of medical education, of securing the enactment and enforcement of medical laws, of enlightening and directing public opinion in regard to the broad problems of state medicine, and of representing to the world the practical accomplishments of scientific medicine." (Article II of the constitution of the American Medical Association.)

*(To be continued.)*

## Medical News.

### ILLINOIS.

**Bequest to Rockford Hospital.**—By the will of the late Eleanor G. Fairchild, \$3000 is bequeathed to the Rockford City Hospital.

**Diphtheria.**—The disease is raging on Campbell's Island, a few miles above Moline, and is causing great alarm there and in Watertown on account of inefficient quarantine.——Nunda has had four deaths.——The schools at Crystal Lake have been closed on account of the disease. Syracuse has five cases.

**Scarlet fever** has spread from Georgetown to Himrod.——The Wingard school at New Village has been closed on account of the disease.——It prevails in Decatur to an alarming extent. In October, November and December there have occurred 84 cases, against 115 cases in the same three months in the ten preceding years. The Board of Health has been appealed to.

**Cottage Hospital to Open.**—The Cottage Hospital, Peoria, which has been erected at a cost of \$125,000, is practically completed and will be dedicated about January 15. It has 100 rooms and two large wards, and has been constructed in accordance with the most advanced sanitary knowledge. It is a model of its kind.

**Smallpox.**—Venice and Granite City on December 30 quarantined against Madison, where 16 cases were found. On the next day the quarantine was raised.——The disease is reported at Boulder, Kansas, Clinton, Blair and Bible Grove townships, near Flora, Beardstown, Buckhart, Sibley and Virginia.——The cost of the recent epidemic to Sangamon County was \$3638.60.

Several new cases are reported at Irvington. The schools have been closed in consequence.

**New State Hospital.**—The new asylum for the incurable insane at South Bartonville, near Peoria, which will be thrown open before February 1, is a group of fifteen large, airy buildings. The institution has just been completed at a cost of approximately \$1,000,000, and the work of furnishing is now rapidly drawing to a close. The asylum occupies a site about five miles south of Peoria, commanding a good view of the valley of the Illinois. The buildings will have immediate accommodation for about 600 insane and 100 hospital patients, but the ultimate capacity of the institution will be about 3000. Dr. George A. Zeller, the superintendent, is now on his way from the Philippines. Dr. Carriel, Jacksonville, will act for him until his return.

#### Chicago.

**St. Luke's Hospital,** in its thirty-eighth annual report, shows that 1818 patients were treated, 35.2 per cent. of whom were charity patients. Legacies of \$32,000 were received during the year. The total receipts were \$100,293, and the expenses \$99,899. There are 21 beds supported by individuals and firms.

**Personal.**—Dr. Adolph Gehrmann has returned from his European trip.—Dr. Eliza H. Root, who has been seriously ill with diphtheria contracted while caring for a relative, is now convalescent.—Corinne B. Eckley has been appointed demonstrator of anatomy in the medical and dental departments of the University of Illinois.

**Diphtheria Lessening.**—The Department of Health reports that diphtheria claimed the fewest number of victims in the year just closed of any in nearly a quarter of a century, notwithstanding a four-fold increase of population during the period. Between 1879 and 1900 inclusive there were 19,002 deaths recorded from this disease—a yearly average of 864, with the lowest number 331 (in 1883) and the highest, 1420 (in 1895), in the fall of which year the antitoxin treatment was begun by the health department. There were less than 500 diphtheria deaths in 1901.

**A Vaccination Creed.**—The Health Department has issued a circular on "Vaccination and Smallpox," on the last page of which the following vaccination creed appears:

We, the undersigned, hereby publicly profess our firm belief—based upon positive knowledge, gained through years of personal experience and study of smallpox and vaccination:

1. That true vaccination—repeated until it no longer "takes"—always prevents smallpox. Nothing else does.

2. That true vaccination—that is, vaccination properly done on a clean arm with pure lymph and kept perfectly clean and unbroken afterwards—never did and never will make a serious sore.

3. That such a vaccination leaves a characteristic scar, unlike that from any other cause, which is recognizable during life and is the only conclusive evidence of a successful vaccination.

4. That no untoward results ever follow such vaccination; on the other hand, thousands of lives are annually sacrificed through its neglect—a neglect begotten of want of knowledge.

ARTHUR R. REYNOLDS, M.D., Commissioner of Health, and HEMAN SPALDING, M.D., Chief Medical Inspector.

These circulars are furnished to lodging houses, police stations, cheap hotels, waiting rooms, factories—in short, to all places frequented by numbers of people, especially of the tramp or migrant class. Attention is called to them by placards, 10x14 inches in size, which contain the text of the vaccination creed. These placards are posted in conspicuous places about the premises and a note at the bottom informs the reader that "further information as to vaccination and smallpox is contained in the 'Supplement to a Vaccination Creed,' copies obtainable on the premises. The placard and circular are proving of much help to the public vaccinators, and the discussions evoked by the *ex cathedra* statements of the 'creed'—which it is sought to explain in the circular in simple phrase and by frequent repetition—are begetting an intelligent interest in the subject of vaccination among classes peculiarly exposed to smallpox.

**Woman's Medical College.**—The daily press for the last few days has contained numerous articles relating to the proposed discontinuance of the Northwestern University Woman's Medical School emanating from more or less authentic sources. There seems still to be doubt regarding the action taken by the trustees of the university in the matter. The secretary of the board, Mr. Frank P. Crandon, on January 6, presented the following "authentic statement":

1. It has been decided to discontinue said department at the end of the current scholastic year.

2. This decision is based upon purely financial considerations. The maintenance of the Woman's Medical School has resulted in such an annual deficit for several years that the university trustees do not feel justified in continuing its operations.

3. The quality of the scholastic work in said department and the attainments and professional excellence of its graduates have always been entirely satisfactory to the university authorities.

4. Neither the board of trustees nor the executive committee has expressed any opinion which is unfavorable to women adopting the medical profession. If individual trustees have announced such a judgment such opinions are to be regarded as personal matters, and not as committing the university to similar opinions or theories.

5. There is no probability that the medical work of Northwestern University will become coeducational.

#### MARYLAND.

**Health Officials Feast.**—The officials of the Baltimore Health Department held a banquet on December 30. Speeches were made by the Mayor, Health Commissioner Bosley and Assistant Health Commissioner C. Hampson Jones.

**State Aid Asked.**—There are 101 institutions asking aid of the state, the total amount asked being \$1,846,840. The applications vary from \$1000 to \$138,000, the latter sum being applied by the Springfield State Hospital for the Insane. Johns Hopkins University applies for \$100,000.

**The Municipal Hospital Commission,** of which Dr. William H. Welch is chairman, has determined to ignore the protests against the building of the Infectious Disease Hospital on the site selected just beyond Druid Hill Park, and if the title be clear to go ahead with the purchase and erection of the building, which is so urgently needed.

**The mortality of Baltimore** for the week ended January 4, was 183,—102 males and 81 females. The principal causes of death were tuberculosis, 22; heart disease, 21; pneumonia, 22; Bright's disease, 19; cancer, 5; typhoid fever, 3, and diphtheria 1. The births were 333, which is accounted for by the fact that many physicians report births only at the end of each month.

**Personal.**—Dr. Ira Remsen, of Johns Hopkins University, was elected President of the American Chemical Society at its recent session in Philadelphia.—Dr. J. C. Coggins of the Maryland Hospital of the Insane, sailed for Europe, January 4.—Dr. Herman Westphal, formerly of the staff of the City Hospital, has returned from Europe.—Dr. Jackson Piper is in Naples.—Dr. William Turner Wooten, late on the staff of the Maryland Hospital for the Insane, Catonsville, has been appointed Assistant Surgeon, U. S. Army.

**Smallpox in Baltimore.**—Baltimore has been particularly fortunate with regard to the smallpox. With one exception all the cases during the past year have been imported. Prompt handling—hurrying the patient to quarantine, vaccinating all those exposed, quarantining infected houses, and destroying infected clothing—has prevented epidemics. During the year the vaccine physicians have examined 17,034 arms and vaccinated 14,385 persons. The department has given particular attention to the inspection of food products, as all milk arriving here or sold, markets, provision stores, bakeries, live stock, stables. Plumbing and drainage are systematically examined; all drinking water is inspected; also coal used by the city, etc.

**Tuberculosis Commission.**—In his message to the legislature the Governor, after pointing to the large mortality from tuberculosis during the past year, and the small provision made for the accommodation of consumptives, says: "I earnestly recommend for your favorable consideration the advisability of creating an unpaid commission to inquire into the presence of tuberculosis in the state, and to devise some means of dealing with it more economically and efficiently than at present. A sufficient sum should be appropriated to pay the expense incurred by said commission in making the investigation." He also recommends "that the duties of the local boards of health be defined and a uniform plan of organization and procedure be provided so that there may be no conflict of authority or divided responsibility in case of emergency."

#### NEW YORK.

**Hospital Endowed.**—The Brooks Memorial Hospital, Dunkirk, has just received an endowment of \$100,000 from Mr. and Mrs. Frederick Stevens.

**State Mortality.**—There were 9309 deaths in this state during November. The Bulletin of the Health Department says concerning smallpox in New York State: "Smallpox has materially decreased since summer, causing ten deaths in September, eleven in October, and nine in November. Six of the deaths occurred outside of the city of New York, one in Buffalo and one in Lockport. During the month it has existed at Syracuse and vicinity; Rochester, Buffalo, Lockport, Utica, Schen-

ectady, Elmira, Binghamton, White Plains and elsewhere. At this time, the end of December, it prevails at Buffalo, Watertown, Middleton, Binghamton and Newburg."

**Anti-Tuberculosis Crusade.**—Sullivan County is instituting a vigorous crusade against the admission of tuberculous patients. The Liberty Board of Health has passed an ordinance imposing a fine of \$50 for maintaining a hospital or sanitarium for consumptives within the village limits. The Board of Health of the town of Rockland has just adopted an ordinance imposing a fine of \$50 on any resident of the town for keeping or harboring a consumptive who is not a member of the family or dependent on them for support. The Board of Health of Monticello has instructed real estate agents to discriminate against consumptives in renting property. At the Loomis Sanitarium for consumptives established four miles from Liberty, through the generosity of J. Pierpont Morgan, hundreds of consumptives are unable to secure admission.

#### Buffalo.

**Personal.**—Dr. George W. Grabenstatter has been appointed a contract surgeon in the U. S. Army and has been ordered to the Philippines.—Dr. Conrad Diehl, who has been mayor of Buffalo for the past four years, will henceforth devote his entire attention to his private practice.

**Appropriations.**—The Committee on Charitable Institutions of the Board of Supervisors recommend that the following amounts be appropriated to hospitals as follows: Buffalo Eye, Ear and Throat Hospital, \$1800; German Hospital Dispensary, \$1500, and Buffalo Eye and Ear Infirmary, \$2200.

**Smallpox Progress.**—At the present time there are 46 smallpox cases in the Quarantine Hospital and since it proves entirely inadequate to the new cases, Health Commissioner Wende and the newly appointed Health Commissioner Green are devising means for a temporary enlargement of the hospital.

**Presentation to Dr. Wende.**—Health Commissioner Wende, on completion of his ten years of public service, was presented with a valuable silver service, by his co-workers in the Health Department. The presentation speech was made by City Chemist Herbert Hill, who spoke of the many advances made in the department under the guidance of Dr. Wende. In appreciation of his services as Health Commissioner, a banquet was tendered him at the Ellicott Club, January 4, at which a beautiful loving cup was presented to him. Dr. Charles Cary was toastmaster and Mr. George P. Sawyer made the presentation speech.

#### New York City.

**The Society of the Lying-in Hospital,** which has been in existence since 1798, came into possession on the first of the new year of the model million-dollar maternity hospital built for it by J. Pierpont Morgan. It is eight stories high, and has 200 beds.

**New Adjutant General.**—Dr. Nelson H. Henry, who has represented the 5th District in Assembly for the past three years, has been appointed by Governor Odell to be Adjutant-General of the National Guard. He is now chief surgeon of the staff of Gen. Roe with the rank of colonel. He served as a division surgeon during the Spanish war.

**Deaths in 1901.**—Out of the 70,808 deaths reported to the Health Department during the year 1901, 8295, or more than one-tenth, were on the records of the morgue. There were 3219 bodies of infants and children under five years consigned to the morgue, but this large number is to be explained by the many deaths occurring at birth in families too poor to bury the little waifs. Last year there were 3857 deaths by accidents, 701 suicides, 105 homicides and 1273 victims of sunstroke. The last item is particularly interesting when contrasted with the 315 deaths from the same cause in 1900. Pneumonia was reported to have caused 9128 deaths and tuberculosis 9396 deaths. While there were only 178 deaths from typhoid fever reported in 1900, there were 729 in the year just closed. The total death rate for 1901 was 20.02 per thousand. There were 80,735 births, or an excess of more than 10,000 over the number of deaths.

#### PENNSYLVANIA.

**Memorial Bed Endowed.**—Mrs. Hannah M. Wright, Washington, D. C., has given \$5000 for the endowment of a bed in the Wilkesbarre City Hospital in memory of Colonel Wright, his first wife, Mrs. Eliza Jones Wright, and their son Joseph B. Wright, assistant surgeon-general, U. S. A., who died last

October. Both Col. Wright and his son were born in Wilkesbarre, and started the practice of medicine in that city.

**Smallpox.**—Two new cases have developed at Marcus Hook.—A second physician of Frankford has come down with the disease.—On account of a case in a boarding house at Lebanon, 40 inmates were held in quarantine.—From McKean Township 9 cases are reported.—Lebanon has 34 cases.—At Hofer 3 cases are reported.—Figart reports 20 cases.—A case is reported from Wyomissing.—New Castle has 7 cases under quarantine.

**Shenango Valley Hospital, New Castle.**—At the annual meeting, Dr. Thomas J. Blackwood was elected president of the staff; Dr. Charles A. Reed, vice-president, and Dr. John Foster, secretary and treasurer. The new medical staff consists of Drs. Albert M. Cook, Thomas J. Blackwood and Harry Wilson; the surgical staff, of Drs. Lewis O. Phillips, Harry W. McKee and Samuel W. Perry. The hospital received \$429.54 as its share of a benefit concert recently held.

**Hospital Moved.**—The East End Hospital, Pittsburg, has been moved to the new building on the Finley property at the Beechwood boulevard and Frankstown avenue, which the Sisters of Charity, who have charge of the hospital, purchased from the Finley estate several months ago for \$100,000. Since the property was purchased, a new addition of about 14 rooms has been made to the Finley homestead, now giving the hospital accommodations for about 28 patients. The hospital property is known as Silver Lake Grove and contains six and three-fifths acres. On this site the new East End Hospital building is to be erected at a cost of \$500,000.

#### Philadelphia.

**Bequests.**—By the will of the late George W. Farr, among many bequests to charity were the following: To the Rush Hospital for Consumptives, \$5000; to the Pennsylvania Hospital, \$10,000, the income to be applied toward ameliorating the condition of the insane poor, by establishing two free beds; for the use of the Wills' Eye and Ear Hospital, \$5000; to the Philadelphia Home for Incurables, \$5000; and to the Polyclinic Hospital, \$2000.

**Smallpox in Philadelphia.**—There were 90 new cases of smallpox and 16 deaths recorded for the week ended January 4. The record is not considered unfavorable, considering the fact that cold weather has prevailed. During 1901 there were in the city 1159 cases of smallpox and 156 deaths, a mortality of 13.45 per cent. Within the week 5 cases were taken from the Philadelphia Almshouse to the Municipal Hospital. There are about 5000 inmates at the former institution, almshouse, hospital and insane department included, and the place has been put under strict quarantine, and only sick, crippled or insane are now admitted. So far, the disease has appeared in one ward only, and it is believed that further spread may be prevented.

#### GENERAL.

**Benguet to be the Mountain Sanitarium of the Philippines.**—The Philippine government has purchased 80 acres near Bagnio, the capital of the Province of Benguet, on which is to be erected a sanitarium. Buildings are to be arranged for reception of sick soldiers. "The high altitude, the bracing temperature never above 80 F., the delicious drinking water, the valuable mineral and hot waters, the gorgeous scenery and the abundant products of the soil, both vegetable and mineral," were interestingly described in THE JOURNAL of Oct. 13, 1900, by Assistant-Surgeon J. C. Minor.

**The American Gynecological and Obstetrical Journal.**—We regret to read in the December issue of this journal that it is to be discontinued. Dr. Emmett has given us a splendid journal; it represented the best in gynecology and obstetrics, and deserved more encouragement than it seems to have had. He has always advocated that which is for the best interests of the profession. Evidently the cause for the discontinuance is a financial one. In the editorial announcing the discontinuance, Dr. Emmett says: "The Journal to-day shows on its credit sheet a balance due from subscribers and advertisers over and above all indebtedness and expenses. It shows also that during the past ten years over 5000 subscribers have received and contracted to pay for this journal and have never paid. It shows further that over \$30,000 have been lost through unpaid subscriptions by contracts freely entered into by medical men. During this time the expenses of the journal had to be met monthly in cash."

**Biometrika.**—The first issue of a new, and in its way unique, high-grade biologic publication, *Biometrika*, has come to hand.

Its purpose is announced to be the collection of "biological data of a kind not systematically collected or published in any other periodical," and also of "spreading a knowledge of such statistical theory as may be requisite for their scientific treatment." It is to be a special organ of those workers, not so numerous at the present time, but increasing, who study statistical questions of biology, such as those raised by the problems of evolution, inheritance, etc. The term *Bionometry* is not a new one, but as a semi-medical specialty it is novel to most of us. The application of mathematics to the problems of life, however, is to be, it seems, a factor in the future development of biologic science and this publication is an evidence of this. Its articles are formidable to the average reader, who is not any too familiar with complex algebraic formulae, but he can appreciate the results when given in plainer language and their application and suggestiveness is apparent. The new journal has as its editorial staff, Professors W. F. R. Wildon, of Oxford, Karl Pearson, of London, and C. B. Davenport, of Chicago, with the well-known author, Francis Galton, as consulting editor. These form the scientific partnership of biologists, mathematician and logical generalizer that, according to the latter, such work requires. It is issued from the University Press, Cambridge, England, in handsome small quarto form, appearing quarterly. It ought to have a cordial reception not only from biologists but also from that considerable class of economic biologists, the actuaries, upon whose field it also largely trenches.

**Memorial Institute for Infectious Diseases.**—In THE JOURNAL for November 16, we announced that one of the wealthy families of Chicago was arranging to endow in a most liberal manner an institute for the study and scientific investigation of infectious diseases. We were not at that time permitted to give the particulars, but stated that the gift was second in importance only to that made by Mr. Rockefeller. We are not at the present time permitted to give the definite amount, but it is very large. The institute is founded by Mr. and Mrs. Harold F. McCormick in memory of their son, John R. McCormick, who died of scarlet fever last year. The object of the institute is the study of infectious diseases, but scarlet fever, its cause and specific treatment will be the primary and chief work of research. The institute is sufficiently endowed to enable these engaged in the task to maintain a number of free beds for scarlet fever patients and to operate a suitable laboratory for pathologic, bacteriologic and animal experimental work. Dr. Ludvig Hektoen has been appointed director of the institute and has selected as one of his assistants Dr. George H. Weaver, of Chicago. For the present the medical members of the board of trustees will be the attending staff. The trustees appointed by Mr. and Mrs. McCormick to manage the institute are Drs. Christian Fenger, Ludvig Hektoen and Frank Billings, and Messrs. Charles L. Hutchinson and Stanley McCormick, the latter a brother of one of the donors. The officers of the board of trustees are Dr. Frank Billings, president; Stanley McCormick, vice-president; Ludvig Hektoen, secretary, and Charles L. Hutchinson, treasurer. The institute has been incorporated and preliminary work already commenced.

**The Proposed National Health Service.**—The following is the text of the bill introduced in Congress:

Be it enacted by the Senate and House of Representatives of the United States of America, in Congress Assembled, That the United States Marine-Hospital Service shall hereafter be known and designated as the United States Health Service, and the supervising surgeon-general and the officers now or hereafter commissioned under the act of January 4, 1889, entitled "An Act to regulate appointments in the Marine-Hospital Service of the United States," are hereby designated as the surgeon-general, surgeons, passed assistant surgeons, and assistant surgeons of the United States Health Service; and the salaries and allowances of said officers, the surgeon-general excepted, shall be the same as now allowed by regulations of the Marine-Hospital Service. Acting assistant surgeons, hospital stewards, and employes shall be continued in employment under the United States Health Service, and shall be employed hereafter under the regulations of said service. Nothing in this act shall be held or construed so as to discharge any officer or employe now serving in the Marine-Hospital Service or to deprive any officer of his commission. The care of sick and disabled seamen and all other duties now required by law to be performed by the Marine-Hospital Service shall hereafter be performed by the United States Health Service, and all funds and appropriations now provided by law for use by the Marine-Hospital Service and all properties and rights pertaining to said service are hereby made available for use, for like purposes and in like manner, under the Treasury Department, by the United States Health Service.

SEC. 2. That the salary and allowances of the surgeon-general of the United States Health Service shall be the same as now allowed by law to be paid to the surgeon-general of the army.

SEC. 3. That commissioned medical officers, when detailed by the surgeon-general for duty in the United States Health Bureau at Washington, District of Columbia, in charge of the administrative divisions thereof, namely, marine hospitals and relief, domestic quarantine, foreign and insular quarantine, personnel and accounts, sanitary reports and statistics, and scientific research, shall, while

thus serving, be assistant surgeons-general, United States Health Service, but their pay and allowances shall be the same as now provided by regulations of the Marine-Hospital Service for officers in charge of said divisions; and the senior officer thus serving shall be the assistant within the meaning of section one hundred and seventy-eight, Revised Statutes of the United States.

SEC. 4. That the President is authorized, in his discretion, to utilize the United States Health Service in times of threatened or actual war, and the commissioned medical officers of said service, while thus serving, or while serving on boards or otherwise brought into official relations with medical officers of the army or navy, shall have rank as follows: The surgeon-general ranking with and after the surgeons-general of the army and navy; assistant surgeons-general ranking with and after assistant surgeons-general of the army and medical directors of the navy; surgeons with and after surgeons of the army having rank of major, and of the navy having rank of lieutenant-commander; passed assistant surgeons with and after assistant surgeons of the army having rank of captain, and of the navy having rank of lieutenant; assistant surgeons with and after assistant surgeons of the army having rank of first lieutenant, and of the navy having rank of junior lieutenant.

SEC. 5. That there shall be an advisory board for the hygienic laboratory provided by the Act of Congress approved March 3, 1901, for the purpose of conferring with the surgeon-general of the United States Health Service relative to the investigations conducted in said laboratory. Said board shall consist of the surgeon-general of the army, the surgeon-general of the navy, the chief of the Bureau of Animal Industry of the Department of Agriculture, and the director of the said laboratory, who shall be *ex-officio* members of the board and serve without additional compensation; and five other members, to be appointed by the Secretary of the Treasury on recommendation of the surgeon-general of the United States Health Service, who shall be skilled in laboratory work in its relation to the public health, and not in the regular employment of the government. The said five members shall each receive compensation of ten dollars per diem while thus serving, together with allowance for actual and necessary traveling expenses and also hotel expenses while in conference, said conferences not to exceed ten days in any one fiscal year. The period of service of the first five of the members not in the regular employment of the government shall be so arranged that one member shall retire each year, the appointments thereafter to be for a period of five years. Appointments to fill vacancies occurring in a manner other than as above provided shall be made for the unexpired term of the member whose place has become vacant.

SEC. 6. That the President shall appoint and commission one chemist, one medical zoologist, and one pharmacologist whenever in the opinion of the surgeon-general commissioned medical officers of the United States Health Service are not available for this duty by detail, who shall be in charge of the divisions, respectively, of chemistry, zoology and pharmacology of the hygienic laboratory, and shall each have the pay and emoluments of a surgeon of the United States Health Service and be subject to the regulations of said service. The director of the said laboratory shall be an officer detailed from the corps of commissioned medical officers of the United States Health Service as now provided by regulations for such detail from the Marine-Hospital Service, and while thus serving shall have the pay and emoluments of a surgeon.

SEC. 7. That when in the opinion of the Secretary of the Treasury the interests of the public health would be promoted by a conference with the State or Territorial boards of health or health authorities, the District of Columbia included, the surgeon-general of the United States Health Service is hereby authorized, with the approval of the secretary, to invite one or more of said boards of health or authorities to send delegates, not more than one from each State or Territory and District of Columbia, to said conference, and when thus convened said delegates shall be entitled to reimbursement for their necessary expenses of travel and of maintenance not exceeding five days at the place of conference, in accordance with such regulations as may be made by the Secretary of the Treasury.

SEC. 8. That to provide uniformity in the registration of mortality, morbidity, and vital statistics it shall be the duty of the surgeon-general of the United States Health Service, after conference with the State boards of health, to prepare the necessary forms for the collection and compilation of said statistics, and said statistics, when transmitted to the United States Health Bureau on the approved forms, shall be compiled and published by the United States Health Service as a part of the health reports published by said service.

SEC. 9. That the President shall from time to time prescribe rules for the conduct of the United States Health Service. He shall also prescribe regulations respecting its internal administration and discipline, and shall prescribe the uniforms of its officers and employes; and the surgeon-general shall transmit annually to Congress, through the Secretary of the Treasury, a report of the transactions of said service.

#### CANADA.

**The Smallpox Situation in Montreal.**—Smallpox is decreasing in Montreal, there being now only 45 patients in the Civic Hospital. There have been 71 cases altogether, and at the present time there are 19 houses in quarantine.

**Montreal General Hospital.**—In the month of December there were admitted into the various wards of the Montreal General Hospital, 175 patients; discharged, 159; deaths, 13; average daily sick in residence, 159. There was a falling off in outdoor consultations and minor operations.

**The Smallpox Situation in St. John.**—It is expected that the outbreak of smallpox at St. John, N. B., will be stamped out in a short time. There are to-day less than thirty persons in quarantine, and one-half of these have recovered. In the three months since the disease manifested itself, there have been 98 cases with 22 deaths.

**Toronto's Vital Statistics.**—The following are the vital statistics for Toronto for 1901: Births, 4445; marriages, 2148;

deaths, 3438. Compared with last year the figures show 85 fewer births, 359 more marriages and 166 fewer deaths. The annual number of births recorded each year for the last nine years is as follows: 4064, 4201, 4131, 4246, 4046, 4122, 4007, 4530, 4445.

**Eddyism Cases Should Be Reported.**—Another death under Eddyite treatment was examined into before a coroner's jury in Toronto last week. In returning a verdict the jury recorded their opinion that means should be taken to compel those practicing Eddyism to report each and every case to the sanitary authorities in order that the necessary precautions should be taken to prevent the spread of contagious diseases.

**Canadian Journal of Medicine and Surgery.**—The fourth annual dinner of the editorial staff of this journal was held in Toronto during the past week. Dr. W. A. Young, the business manager, presiding. Crown Attorney Curry, in responding to the toast of the legal profession, hoped to see legislation soon passed which would effectually rid the city of quacks, fakirs and such-like when have infested this city too much of late.

**Fakirs Infesting Toronto.**—Toronto seems to be overrun with palmists, osteopaths, Eddyites and other "healer" at the present time, if one is to judge from the almost daily prosecutions in the police court. One of the latest frauds exposed is what is known as the "Radiant Health Circle." One could travel in on one of the rays for the usual dollar. Two of these have been convicted of obtaining money under false pretenses and are at present awaiting sentence.

**Insane in Toronto Gaol.**—In the recent presentation of the Grand Jury of the County of York, Province of Ontario, mention is made of the fact of there being 60 lunatics confined in the Toronto Gaol. The report continues that the hospitals are also crowded, and it would appear as though the city had outgrown accommodation for these classes of the community. In the House of Providence, 60 consumptives are being attended to. This was the only charitable institution which would provide for the latter before popular demand opened the hospitals again to the consumptive.

**Toronto Clinical Society.**—The regular meeting of the Toronto Clinical Society was held on the evening of the 3d inst., Dr. J. F. W. Ross presiding. Dr. George A. Peters reported three cases. The first was a case of esophagotomy in a young man who, while in the act of drinking a cup of tea, swallowed a dental plate with one tooth from the middle of the upper row. Other means failing for its extraction, an operation was performed along the left frontal border of the sternomastoid. The plate had become lodged just above the cricoid, the two lateral prongs being caught transversely in the walls of the esophagus. The patient made an excellent recovery. Dr. Peters showed a phopthatic calculus weighing 6 ounces, extracted suprapubically, and described his method of cutting calculi.

**Personals.**—At an open meeting of the Pathologic Society of Toronto, held on the evening of January 4, Dr. J. George Adams, of McGill University, was present and read a paper on the "Classification of Tumors."—Dr. W. H. Drummond, of Montreal, the author of "L'Habitant" and other poems, will deliver the opening lecture of the University Saturday Lectures at Toronto on January 18.—Surgeon-Major Duff, of Kingston, will accompany the Third Contingent from Canada for service in South Africa, as assistant surgeon.—Dr. William J. Abbott, of Brockville, who is at present taking a post-graduate course in England, has been offered and has accepted a professorship at Cornell University, and will return this month to enter on his new duties. Dr. Abbott is a graduate of Toronto University.—Dr. Doughty, of Quebec, has been appointed joint librarian with Dr. Dionne, of the legislative library of the province of Quebec.

## FOREIGN.

**Professor Virchow Injured.**—On January 5, as Professor Virchow was alighting from a Berlin street car, he fell and the right femur was broken.

**Surgeon-General von Leutholdt** has been appointed a salaried professor in the medical faculty of the University of Berlin. He thus succeeds the late Surgeon-General Kohler likewise in the university.

**Suspension of the "Klinichesky Journal."** The suspension of this medical journal, published monthly at Moscow during the last three years, is announced. It contained several features that will be much missed.

**A Million Dollars for Tuberculosis Sanitarium.** Sir Ernest Cassel, merchant and financier, has placed £200,000 at

the disposal of King Edward, to be devoted to the erection and maintenance of a sanitarium for tuberculous patients. The king has appointed the following physicians as an advisory committee: Sir William Henry Broadbent, Sir Richard Douglas Powell, Sir Hermann Weber, Sir Francis Laking and Dr. Charles Theodore Williams.

**New Russian Medical Weekly.**—The first number of the *Russky Vrach* is an imposing journal of 48 pages and nearly a dozen separate departments. Seven pages are devoted to an indexed review with brief summary of the medical periodicals of Europe, England and America and also of these presented at the Russian universities. As our readers remember, the *Vrach*, published at St. Petersburg, is discontinued this year, according to the will of its founder, Dr. Manassein, and this new periodical will take its place, with several new features. Professor Podwyssotzki, of Odessa, and Dr. Vladislavleff, of St. Petersburg, are the editors.

## LONDON LETTER.

### The Smallpox Outbreak Still Progressing.

The outbreak of smallpox still continues to progress. There are now 569 cases in hospital. The Metropolitan Asylums Board—a body which manages the fever hospitals—takes a very gloomy view of the outlook. A feeling of uneasiness exists that London may be on the eve of a visitation of greater magnitude than has been experienced for many years. The accommodation now existing consists of hospital ships with 250 beds, two hospitals containing respectively 1000 and 190 beds, and one in course of erection containing 300 beds—total, 1740 beds. Another hospital of 94 beds is in course of erection, but is not sufficiently advanced to be regarded as an available resource. The erratic behavior of smallpox, its sudden fluctuations and the unforeseen rapidity with which it sometimes progresses, constitute the real danger and baffle all efforts to provide an estimate. The Board, after careful consideration, has come to the conclusion that not fewer than 2500 beds should be the minimum, which should be forthcoming in the next few months, i. e., 1000 more beds should be provided. Instructions have been given to architects to immediately prepare schemes for further hospital construction at an estimated cost of \$85,000.

### Vaccination and the Outbreak.

It has been pointed out in THE JOURNAL that the great neglect of vaccination is largely responsible for the outbreak. Analysis of the statistics of the cases which have occurred is instructive, though it only confirms the well-attested value of vaccination. Since May, 349 cases have ended either in recovery or death. Of these 116 were fatal. The death-rate in the unvaccinated was thrice that in the vaccinated. The patients under the age of 5 were all unvaccinated; there were 23 with 19 deaths. The patients under 10 were all unvaccinated except one. Here out of 42 cases, 29 were fatal, and all those who died were unvaccinated. There were 81 cases in patients under 15, and 38 deaths; 57 of the 81 were unvaccinated. Of the 38 who died only one was vaccinated; so that of the 24 who were vaccinated, 23 came safely through the disease.

### How London Copes with Infectious Diseases.

A description of the method of dealing with infectious disease of this vast metropolis, of over 5,000,000 of people, should be of special interest at the present time, as smallpox is now prevalent. The Metropolitan Asylums Board system is of its kind probably the finest organization in the world. It dates from 1867, when it was instituted to relieve the Guardians of the Poor of the care of imbeciles and fever patients who could not properly be treated in workhouses. It consists of 72 members, 54 of whom are elected by various boards of guardians, and 18 by the Local Government Board. They spend \$3,500,000 annually and provide 5 services: 1, infectious hospitals; 2, ambulance service; 3, imbecile asylums; 4, training ships, and 5, state-supported children. The infectious hospitals number ten, and contain 4421 beds; in addition there are two hospitals for convalescents, containing 1464 beds. There are also the smallpox hospitals, which have been described above. All the hospitals are as well equipped as any in the world. There are six ambulance stations on hand, each containing a staff, male and female, harness rooms, coach houses, stables, carriages, etc. In a case of infectious disease the doctor writes out a certificate stating its nature and all particulars, as to address, age, sex, etc. These particulars are sent by telephone to the nearest ambulance station, and almost as smartly as the fire brigade turns out, an ambulance, containing a trained nurse, is dispatched to the patient's house. If the patient is over the age of 10, a male attendant is also sent. Restoratives and refresh-

ments are carried in case they should be required for prostrate patients. The ambulances are most carefully constructed, and if necessary, are kept warm. Smallpox cases are taken to a wharf on the river, of which there are three, where they are met by one of the four paddle-wheel ambulance steamers. One of the latest built of these steamers is a steel vessel 143 feet long, 22 feet in breadth, with a five-foot draft, and 263 tons displacement. It is beautifully fitted up for the conveyance of 52 patients in a recumbent position. The steamer proceeds down the river at 14 knots an hour, the voyage occupying one and a half to two hours. During the years 1884 to 1899, over 16,000 patients have made this journey. The hospital ships occupy an isolated position in Long Reach, nearly 17 miles from London Bridge. An adjacent portion of land has been purchased, on which there has been built a laundry, accommodation for nurses, and an engine and dynamo house for electric lighting. The isolation of the patients in these floating hospitals has had immense advantages, but there are certain disadvantages, not the least of which is the liability to injury from passing craft in foggy weather, and the disastrous results likely to follow a serious outbreak of fire.

#### A Medical Hero.

A sad tale of the heroism of a physician in his medical work has riveted the attention not only of the profession, but of the whole people. Dr. William Smyth was dispensary physician of a district in Donegal, Ireland, which includes the Island of Arranmore, about four miles from the mainland. Its inhabitants are very poor peasants, with little notion of sanitation. An outbreak of typhus fever occurred among them. Owing to the terror inspired by the disease, Dr. Smyth could obtain no help in fighting against it. Alone each day he rowed in his boat across the stormy waters of the sound to the island. Alone he tried to perform the duties of both nurse and doctor for the sick in their miserable homes. He decided that the only chance of recovery lay in removing the patients to the mainland. But the fishermen were afraid to help him. Dr. McCarthy, government medical inspector, arrived on the scene. The two physicians brought the patients ashore in a leaky boat. The patients all recovered, but Dr. Smyth contracted the fever and died. He left a widow and eight children unprovided for. But a committee has been formed of the Ulster physicians and other influential persons to collect subscriptions for his family, and the movement has spread to England. Already it is evident that a generous response will be made to the appeal, and that his family will not suffer monetarily by his heroic devotion to duty.

## Correspondence.

### Official Control of Antitoxins and Vaccines.

CHICAGO, Jan. 2, 1902.

*To the Editor:*—The paper of Dr. Dock on "Smallpox and Vaccination" and the editorial comment thereon, "The Vaccination Question," in THE JOURNAL of December 21, following so closely the antitoxin episodes, suggests more forcibly than ever the necessity for some authoritative method of inspection and control of these remedial agents.

As has been observed, in the absence of some form of supervision or restriction by the National Government on the manufacture and sale of these biologic products the medical profession through its National Association should take the initiative and provide some means whereby the absolute identity, purity and degree of potency of at least these delicate and variable organic preparations will be assured beyond peradventure.

As is well known, the United States Pharmacopeia is now undergoing the eighth decennial Revision by a National Committee of Physicians, Chemists and Pharmacists. While this committee has recognized the desirability of admitting sera and similar products, the lack of any method within reach of ordinary pharmaceutical practice whereby their identity, purity and degree of potency may be confirmed, has been a well-nigh unsurmountable obstacle and their admission consequently held as contrary to the principle upon which Pharmacopeias have been constructed the world over since their inception.

The pharmaceutical profession, including the manufacturers, is no less anxious than the physicians to secure that uniformity in these agents which shall render their administration safe

and the confidence in their efficacy by the public be maintained paramount. It naturally turns to the Pharmacopeia, since the U. S. Ph. is the only legal standard authority for medicines in every state in the Union, as well as in the medical branches of the National Government.

In view of the transcendent importance of this question it is believed that the time has now come when the American Medical Association should constitute a committee to confer with the National Committee of Revision of the U. S. Ph. for the purpose of creating a Bureau or some central authority for the inspection and control of antitoxins and vaccines. Possibly some arrangement could be made with the Bureau of Animal Industry or similar related institution.

The question of antitoxins has been solved in Germany by introducing it in the Pharmacopeia and prescribing certain rules for its examination and sale through a central controlling laboratory in Frankfurt on the Main.

The following is the introductory to the text:

*Serum Antidiphthericum—Diphtheric-Heilserum.*

Arzneibuch für das Deutsche Reich (1900).

Pharmacopœia Germanica, Editio IV.

Blood Serum from horses which are immune against diphtheria. Derived from accredited manufacturing places after it has been tested for its immunizing unit-contents, absence of germs and amount of preserving agents (phenol or tricoresol) and has been approved for sale by the Royal Prussian Institute for Experimental Therapy in Frankfurt on the Main.

It occurs in liquid and in solid form. In either form this Serum must be dispensed in vials only, with the official hermetic seal, with the name and place of manufacture.

Stating: The antitoxin contents of one cubic centimeter, the total contents of one vial, the control number and the day of its official examination.

These vials are packed so as to exclude the light; in packages which also give the above mentioned information.

The seals bear on one side an eagle or a lion. The other side gives the number of the total contents of immunizing units, I. U. (I. E. Immunisierungseinheiten.)

Hoping that THE JOURNAL, through the great Association it represents and the medical profession in general, will take this matter into consideration at once, I am, very truly,

C. S. HALLBERG,

Secretary Section Materia Medica, Pharmacy and Therapeutics; Member of Committee of Revision of the U. S. Ph.

### Administration of Immunizing Serum by Mouth.

ST. LOUIS, Mo., Jan. 6, 1902.

*To the Editor:*—I notice in THE JOURNAL of Jan. 4, 1902, an editorial headed: "The Administration of Immunizing Serum by Mouth," in which remarks in a little paper of mine published lately are commented upon in such an incorrect way that I can not refrain from asking you to insert this.

You certainly glanced only superficially at my paper; otherwise you would have found that I did nothing but assert that a still greater number of tetanus cases would have occurred during the late accident had not the tetanus toxin containing diphtheria antitoxin been administered by the mouth; so that in some and the same family the diphtheria patient injected subcutaneously died of tetanus, while the other members of the family immunized by "taking the serum per os escaped." I fail altogether to see how you have arrived at the idea that I had observed any effect of this internal administration of the serum other than negative.

As to the scientific side of the question of administering antitoxin by mouth, I would direct you to Römer's paper in the *Berl. Klin. Wochenschr.*, No. 46, 1901.

C. FRISCH.

[The editorial was based, so far as concerned our correspondent's paper, on the following passage: "In at least fifteen cases the development of tetanus was prevented by the administration of the serum by the mouth. These were all cases in which it was intended to immunize the members of the family surrounding the diphtheric individual." The context does not make inexcusable the impression that we received from the above statement as it apparently argues for the possibility of toxins and antitoxins being absorbed by the mucous membranes of the digestive tract in children. The concluding sentence of the article, "Although in our case this form of antitoxin administration was a very fortunate quid pro quo, it is not to be recommended as a generally indicated method," may

perhaps also be taken to convey the meaning as understood by us. It appears from his explanation that the subjects escaped tetanus in 15 cases because they took the serum only by the mouth and did not absorb it. They were cases of non-exposure; therefore, it seems hardly correct to say that the development of tetanus was prevented. If the article had read "avoided" or "escaped" instead of "prevented" the misunderstanding would not have occurred. We admitted a certain lack of understanding of the passage in the editorial and now accept the correction. Our editorial was simply intended to be a little less obscurely sarcastic as to this particular method of immunization than it appears was his article on this special point. EDITOR.]

## Book Notices.

MEMOIRS AND LETTERS OF SIR JAMES PAGET. Edited by Stephen Paget, One of His Sons. With Portraits and Other Illustrations. Cloth. Pp. 438. Price, \$5.00. New York and Bombay: Longmans, Green & Co. 1901.

The biography of a great man, one who has obtained his greatness by his own efforts, is always a stimulus to those who read it. This is true of the life of Paget. It gives us the aims, ambitions, personality and method of work of one who had added luster to our profession by hard work under extreme difficulties. Although he died only two years ago, Paget seems to belong to a past era in medicine, and in one sense this is so. His great work on Surgical Pathology—the book that bridged the medicine of the past with that of to-day—published in 1853, nearly fifty years ago. Born at a seaport town, Yarmouth, his boyish fancy was for the navy, and it was only by the merest accident that this fancy was not gratified. His next great attraction was botany, and in this he gained quite a reputation in his youth, collaborating with his brother in writing a description of the flora of his neighborhood. But this he realized was not a very satisfactory life-work, and he succeeded in getting apprenticed to a local surgeon, and in 1834 entered Bartholomew's, London, receiving his M.R.S.C. in 1836. Then came the "waiting time" as he expresses it, but in reality it was a working time. He was now poor, and dependent on himself, for his father had lost everything. Left to his own resources, his indomitable energy showed itself. His ambition decided him to stay in London, and as practice was naturally slow in coming he went to work writing translations and instructing any stray pupil that he could get. This was in addition to the scientific work he was carrying on. He tells us that his total receipts from practice during his first seven years was less than \$700. "During the first seven years after obtaining my diploma my largest income from practice was £23 13s." But then came a change, for he tells us that at one time his annual income exceeded £10,000. This success came though after many years of hard work, work that allowed him only four or five hours sleep, and often not that much.

The book consists of an autobiography—interesting, but much too brief—and letters, with comments by his son. These give us an idea of the man as a private individual, as a great surgeon and teacher, and as an honorable member of the profession he loved. They also give an insight into the reason for his greatness—his indomitable energy and tireless work. The book tells us of the beginnings and the early developments of modern pathology, and presents the methods of work and the personality of the man who did so much for it. While the book is as interesting as a novel, above all it is instructive.

TYPHOID AND TYPHUS FEVERS. American Edition of Nothnagel's Encyclopedia. By Dr. H. Curschmann, of Leipzig. Edited, with additions, by William Osler, M.D., Professor of the Principles and Practice of Medicine, Johns Hopkins University. Handsome octavo of 646 pages, illustrated, including a number of valuable temperature charts and two full-page colored plates. Cloth, \$5.00 net. Philadelphia and London: W. B. Saunders & Co. 1901.

One of the best systems of medicine in any language is Nothnagel's Encyclopedia, heretofore a closed book to those who do not read German. Its reproduction in English will be heartily welcomed by all who know the work by reputation, and the thanks of the English-speaking profession are due the publishers for their enterprise in placing this magnificent

work before them. If the first volume on typhoid and typhus fevers, now before us, is a fair sample of those which are to follow, then, indeed, shall we have a series of monographs surpassing even the original. The first volume contains 646 pages, 472 of which are devoted to the discussion of typhoid fever. The general character of this work is so well known that it would be superfluous for us to take space to enlarge upon its general character. We can say, however, that under the editorial supervision of Dr. Osler, the original German work, excellent though it is, has been much improved, greatly enlarged and enhanced in value, especially to American readers. The work is much more than simply a translation of the original, for it contains additional matter in nearly every chapter. The recent work of Americans has especially been recognized and incorporated in this monograph. Taking it all in all, the monograph on typhoid fever is the best exponent of the knowledge that we have in regard to this disease that is to be had in any language. The publishers have done their part well, the book making an excellent appearance. It is especially well and artistically bound, printed on paper above the average, so that all in all, the book is worthy of the highest commendation.

## Married.

S. H. CORDONIER, M.D., Avilla, Mo., to Miss Hattie Wise of Tamaleo, Ill., December 20.

ROBERT D. SISTRUNK, M.D., to Miss Corinne Coleman, both of Dade City, Fla., December 24.

PAUL C. RIETZ, M.D., Evansville, Ind., to Miss Ida Lauppe of Seward, Neb., December 25.

ELMER E. HAYNES, M.D., Belpre, Kan., to Miss Luella Adams of Abilene, Kan., December 25.

J. LEONARD JENNINGS, M.D., Danville, Va., to Miss Mary M. Ogle, at Baltimore, December 25.

HENRY A. BLAIR, M.D., San Antonio, Texas, to Miss Lillian Kratz, Edmundson, St. Louis, Mo.

THOMAS MOATE, M.D., to Miss Anna Rich, both of Gridley, Ill., at Enreka, Ill., December 19.

PAUL VAN RIPER, M.D., Beacon, Mich., to Miss Edyth A. Gage of Niles, Mich., December 25.

ELMER U. WOOD, M.D., Columbus, Ind., to Miss Minerva Bates of London, Ohio, December 26.

LOUIS J. C. BAILEY, M.D., Stonega, Va., to Jean Cruickshank, M. D., Toronto, Ontario, December 24.

WILLIAM C. PRESSLY, M.D., Troy, Tenn., to Miss Cammie Brice of Union City, Tenn., December 19.

EUGENE C. LINDSAY, M.D., Tusculum, Ala., to Miss Emily White of Belle Mina, Ala., December 17.

PETER JOHN, M.D., Laurinburg, N. C., to Miss Nannie Watkins of Charlotte County, Va., December 24.

ELEANOR CAPITOLA READ, M.D., Peru, Neb., to Julian D. Graves of Hillsdale, Iowa, December 30.

HORACE L. JONES, M.D., Waggoner, I. T., to Miss Nannie May Hunt of Adair, Tenn., December 27.

JAMES BRAINARD CROFF, M.D., to Carro Julia Cummings, M.D., both of Buffalo, N. Y., December 24.

AUGUSTUS SARGENT BOLSTEP, M.D., to Miss Georgia Louise Houghton, both of Worcester, Mass., January 1.

JOHN DE MOTTE MILLER, M.D., Leavenworth, Kan., to Miss Florence Reasoner, at Ypsilanti, Mich., December 20.

S. P. HART, M.D., Waverly, Ill., to Miss Nola May Fletcher of Auburn, Ill., at Springfield, Ill., December 18.

WARREN H. HUNTER, M.D., to Miss Louise V. Greenwood, both of Chicago, at St. Joseph, Mich., December 31.

THOMAS A. JOYCE, M.D., to Miss Jennie B. McCaffrey of East End, Pittsburg, Pa., at Sheraden, December 28.

WILLIAM LUTHER SHOLLENBARGER, M.D., Cincinnati, Ohio, to Miss Carolyn Faber of Westwood, Ohio, December 18.

RALPH C. TILLEY, M.D., to Miss Annie Dorrel, both of Petersburg, Ky., at East Enterprise, Ind., November 28.

C. W. GREEVER, M.D., North Tazewell, Va., to Miss Nannie, daughter of Dr. Thomas G. Witten, Tazewell, December 25.

CHARLES WILBUR HEDGES, M.D., Newkirk, Okla., to Miss Pearl Atchison Carmichael of Nashville, Tenn., December 25.

MARTIN PEMBROKE CONGDON, M.D., Binghamton, N. Y., to Miss Hortense Josephine Coyne, of Scranton, Pa., December 26.

ROBERT PEYTON LACKEY, M.D., Nagadoches, Texas, to Miss Mittaise Pausy Holt of West Nashville, Tenn., December 25.

OTTO F. WELLENREITER, M.D., Quincy, Ill., to Miss Mary Etta Mohler of Washington, D. C., at Quincy, Ill., December 25.

CHARLES M. FREEMAN, M.D., Metucken, N. J., to Miss Mary E. Wilkins of Randolph, Mass., at Metucken, N. J., January 1.

DAVID HARRY RUTHERFORD PATTON, M.D., Chicago, to Miss Mary Ellen Fallon of Oshkosh, Wis., at Chicago, December 23.

ROBERT A. RANGE, M.D., Elizabethton, Tenn., to Miss Mary E. Emert of Keensburg, Tenn., at Harmony Church, December 2.

FREDERICK NELSON TANNER, M.D., Vienna, Dorchester County, Md., to Miss May S. Purcell, at Baltimore, December 17.

WILLIAM BURNHAM FISK, M.D., Chicago, to Miss Georgia Antoinette Denger of Elm Grove, Fond du Lac, Wis., December 31.

GEORGE WILLIAM SHERA, M.D., to Miss May Finley Bishop, both of Jersey City, N. J., at Trinity Church, New York, December 18.

HARRY EDWIN WILLIAMS, M.D., Milton, Mass., to Miss Emma Josephine Tyler of Mount Vernon, Mass., at Augusta, Maine, December 25.

BERNARD HEATH EARLY, M.D., Blue Ridge Springs, Va., to Miss Bernardine Peyton Llewellyn, a trained nurse, at Baltimore, January 2.

## Deaths and Obituaries.

**Duncan McLeod, M.D.** Detroit Medical College, 1873, one of the best-known physicians of Detroit, ex-health officer of the city, a member of the faculty of the Detroit Medical College, and for twenty-two years a practitioner of the city, died December 29, at his home, from pleuro-pneumonia, after an illness of two weeks, aged 53. The Wayne County Medical Society called a special meeting, December 31, at which resolutions were adopted, stating that "as a physician and as a citizen he held positions of honor and trust, which he discharged with fidelity, and in the closer relations in which it was the privilege of this Society to know him, the innate qualities of a generous heart, an honorable character and an amiable nature were fully revealed."

**Oscar Dunreath Abbott, M.D.** Berkshire Medical College, Pittsfield, Mass., 1850, a prominent figure in medical circles in New England for half a century, died at his home in Manchester, N. H., after an illness of two months, following an attack of la grippe, January 1, 1902, aged 77. He had served as city and county physician, as a member of the Board of Health and was a member of the State Medical Associations of Massachusetts and New Hampshire, and the Manchester Medical Association, and was consulting physician to the Elliot Hospital.

**Lewis Evans Carson, M.D.** Medical College of Evansville, Ind., 1876, chaplain of the 98th Indiana Infantry during the Civil war, and since 1876 in active practice in Prairieton, Ind., died at his home in that place, December 29, aged 77. He is said to have been the "friend, physician and pastor" of almost everyone in the township. He was a member of the Vigo County Medical Society and of the Esculapian Society.

**Leroy A. Merrill, M.D.** University of Vermont, Burlington, 1882, for many years a practicing physician in Lonsdale, R. I., died at his home in that village, December 23, from typhoid fever, after an illness of three weeks, aged 46. He was a member of the Pawtucket Medical Society and the Rhode Island Medical Society, and was coroner and health officer of Lonsdale for several years.

**Henry Fitzbutler, M.D.** University of Michigan, Ann Arbor, 1872, the first colored regular practitioner to settle in Kentucky, dean and professor of materia medica and surgery in the Louisville National Medical College, and surgeon to the Auxiliary Hospital, died at his home in Louisville, December 28, from chronic bronchitis of six years' duration, aged 64.

**Frederick M. Barrows, M.D.** Geneva (N. Y.) Medical College, 1846, a resident of Clinton, N. Y., for nearly 70 years,

and a practitioner for 55 years, died at his home in that place, December 27, aged 79. Until a year ago he was in active practice, but at that time he suffered a stroke of paralysis, and a few months later became totally blind.

**George D. McIlwaine, M.D.** Western Pennsylvania Medical College, Pittsburg, 1895, a practitioner of Washington, Pa., who served in the Spanish-American war with the 10th Pennsylvania Infantry, U. S. V., in the Philippines, died at the residence of his father in Pittsburg, December 25, from Bright's disease, after a short illness, aged 35.

**Amos C. Lewis, M.D.** Cincinnati College of Medicine and Surgery, 1871, a well-known dermatologist of New York City, formerly medical superintendent of the Skin and Cancer Hospital, and at the time of his death visiting physician to the Fordham Hospital, died at his home in New York, December 28, after an illness of five weeks, aged 59.

**James Snyder Mackie, M.D.** College of Physicians and Surgeons, Baltimore, M.D., who practiced for several years in Baltimore, but entered the diplomatic service of the United States in 1851, remaining therein until 1864, died at his home in Newark, N. J., from apoplexy, after an illness of two days, December 30, aged 77.

**John Geyer, M.D.** University of Wooster, Cleveland, Ohio, 1876, a prominent German practitioner of Dayton, Ohio, died at his home in that city, December 29, after a long and painful illness, aged 56. At a meeting of the Montgomery County Medical Society, December 23, a memorial to Dr. Geyer was drafted and adopted.

**George C. Devine, M.D.** Jefferson Medical College, Philadelphia, 1882, who served as apothecary in the United States Navy until 1886, and then practiced in Philadelphia, where for the last 12 years he was police surgeon, died at his home in that city, December 26, after an illness of one week, from pneumonia, aged 43.

**James M. Wallis, M.D.** University of Pennsylvania, Philadelphia, 1847, a well-known physician of Philadelphia, died at his home in that city, December 28, aged 77. He served as surgeon throughout the Civil war, and at its close returned to Philadelphia, where he practiced until twenty years ago, when he retired.

**Isaac T. Monroe, M.D.** Albany (N. Y.) Medical College, 1866, a prominent physician of Granville, N. Y., and a member of the Washington County Medical Society, died at his home in Granville, December 29, after a prolonged illness, from bronchial pneumonia, aged 61.

**M. W. Hamilton, M.D.** Tulane University, New Orleans, a member of the Little Rock, Ark., Medical Society, died recently at that place. The Society passed resolutions expressive of its loss and of its sympathy for the bereaved relatives, at a meeting held January 2.

**T. H. Wright, M.D.** Louisville (Ky.) Medical College, 1873, for many years a practitioner of Pickens, Miss., died at the residence of his daughter in Washington, D. C., December 24, from Bright's disease, after a protracted illness.

**Frank A. Farrell, M.D.** Jefferson Medical College, Philadelphia, 1893, a practitioner of Wilkesbarre, Pa., died, December 29, at Deming, N. M., where he had gone for his health a year ago, from pulmonary hemorrhage, aged 35.

**John R. Wood, M.D.** Medical College of Virginia, Richmond, 1864, one of the most prominent physicians of Albemarle County, Va., died recently at his home in White Hall, Mooreman's River, from Bright's disease, aged 63.

**Charles J. Barnum, M.D.** Tuft's Medical School, Boston, 1901, an interne at the Boston City Hospital, died at that institution, January 2, after an illness of three weeks, from typhoid fever, aged 21. He was a native of Chicago.

**James L. Titterton, M.D.** Missouri Medical College, St. Louis, 1886, for several terms a member of the legislature and a pioneer citizen of La Clede County, died at his home in Richland, Mo., December 25.

**Frank M. Cronin, M.D.** University of Pennsylvania, Philadelphia, an old and esteemed practitioner of Lancaster, Wis., died suddenly in his office in that city, from heart disease, December 25, aged 55.

**Thomas A. Joyce, M.D.** West Penn Medical College, Pittsburg, whose marriage on December 28 is noted in this issue, died at his home in Sheraden, Pittsburg, December 31, aged 30.

**Samuel C. Webb, M.D.** Albany (N. Y.) Medical College, 1854, who had practiced medicine for nearly 25 years in Homer, N. Y., died at his home in that place, December 29, aged 83.

**Milton P. Mason, M.D.** Western Reserve University, Cleveland, Ohio, 1854. one of the oldest residents of Mansfield, Ohio, died suddenly at his home in that city, December 26, aged 72.

**Samuel H. Hudnall, M.D.** New York University, 1852, who had practiced medicine in Campbell County, Va., for more than 40 years, died recently at his home in Brookneal, aged 75.

**Emily A. Benn, M.D.** University of Michigan, Ann Arbor, 1892, an able practitioner of Ypsilanti, Mich., died at her home in that city, January 2, after a long illness, aged 41.

**Abby J. Wolverton, M.D.** University of Nashville, Tenn., 1878, a prominent practitioner and capitalist of Indian Territory, died at his home in Ardmore, December 28.

**P. J. McCaffrey, M.D.** Vanderbilt University, Nashville, Tenn., 1899, who practiced in Ashland, Pa., and thence removed to Cleveland, Ohio, died recently, aged 23.

**Frank E. Webb, M.D.** University of Nashville, Tenn., 1882, died at his home in Nez Perce, Idaho, December 21.

## Association News.

### New Members.

The following is a list of new members for the month of December, 1901:

#### ALABAMA.

Dennis, G. A., Montgomery.

#### ARKANSAS.

Cuffman, J. H., Gurdon.  
Douglass, T., Ozark.  
McConnell, J. W., Huntington.  
Stanley, W. T., Selma.  
Wallis, Jas. C., Arkadelphia.

#### CALIFORNIA.

Barry, W. T., Salinas.  
Canao-Marquis, F. P., San Francisco.  
Hitchcock, Los Angeles.  
Hutchinson, G. L., Los Angeles.  
Ross, Thomas, Sacramento.

#### COLORADO.

Trout, A. L., Berwind.  
Zodorbau, A., Denver.

#### CONNECTICUT.

Jennings, G. H., Jewett City.  
Lawrence, G. W., East Berlin.  
Monagan, C. A., Waterbury.  
Nettleton, F. L., Shelton.

#### DISTRICT OF COLUMBIA.

Johnston, W. W., Washington.  
White, C. S., Washington.

#### GEORGIA.

Crawford, O. G., Sasser.  
Toepel, T., Atlanta.  
Wright, J. E., Macon.

#### IDAHO.

Kinnaird, Wm., Idaho Falls.  
Conant, Jr., J. L., Genesee.  
Morris, J. B., Lewiston.  
Schaff, C. W., Lewiston.

#### ILLINOIS.

Allen, F. M., Chicago.  
Baumgartner, M. M., Freeport.  
Brooks, E. W., Altamont.  
Caspers, Paul, Chicago.  
Earle, F. B., Chicago.  
Easley, W. T., Greenville.  
Glasgow, E. A., Mulberry Grove.  
Greenfield, C. E., Chicago.  
Hall, Andy, Mt. Vernon.  
Hillmanow, J. T., Chicago.  
Miner, E., Champaign.  
Nash, F. W., Big Rock.  
Pierce, F. E., Chicago.  
Smith, I. C., Stockton.  
White, Earl C., West Brooklyn.

#### INDIANA.

Alexander, W. P., Gas City.  
Bowell, Bo., La Porte.  
Brittain, S. H., Logansport.  
Cochran, T. C., Sharpsville.  
Evans, F. A., Tell City.  
Foxworthy, Frank W., Indianapolis.  
Houghland, Chas. S., Milroy.  
Kerdle, G. C., Princeton.  
McClurkin, J. C., Evansville.  
Sutherland, P. N., Angola.

#### IOWA.

Bay, H. H., Marshalltown.  
Cornell, C. W., Knoxville.

Farnsworth, D. W., Galva.  
Hamilton, A. S., Independence.  
Lukens, J., Oskaloosa.  
McConaughy, W. D., Prairie City.

McKaig, R. F., Wever.  
Payne, Harry C., Leighton.  
Payne, C. W., Boone.  
Ransom, W. L., Granger.  
Singleton, E. M., Marshalltown.  
Stratton, M. R., Cleveland.  
Tribbet, J. C., Montezuma.

#### KANSAS.

Atkin, E. N., Olmitz.  
Cheney, E. R., Gypsum.  
Sandidge, J. H., Mulberry.  
Smith, C. A., Yale.

#### KENTUCKY.

Cox, B. D., Jackson.  
Frather, H. E., Hickman.  
Taulbee, J. B., Maysville, Macon County.

#### LOUISIANA.

Barrier, J. M., Delhi.  
Cline, Isaac M., New Orleans.  
Minus, David D., Crowley.  
Sabatin, G. J., New Iberia.

#### MAINE.

Barker, F. N., Norway.  
Binford, H. J., Mexico.  
Chamberlain, A. H., Foxcroft.  
Campbell, G. R., Augusta.  
Chapman, H. M., Ashland.  
Gribben, H. E., Augusta.  
Higgins, Lella, Livermore Falls.  
Hill, H. B., Augusta.  
Sweet, A. W., Bangor.  
Wadsworth, J. E., Skowhegan.

#### MARYLAND.

Buffington, J. A., New Windsor.  
Halsted, W. S., Baltimore.  
Hinebaugh, M. C., Oakland.  
Kirby, F. J., Baltimore.  
Pancoast, O. B., Baltimore.  
Sawdrock, W. Christian, Baltimore.  
Smith, F. R., Baltimore.

#### MASSACHUSETTS.

French, C. L., Clinton.  
Hopkins, F. E., Springfield.  
McGannon, T. G., Lowell.  
Moigs, R. J., Lowell.  
Morse, C. E., Wareham.  
Robertson, W. B., Belmont.

#### MICH.

Conley, W. C., Ishpeming.  
Cowie, D. M., Ann Arbor.

#### MINNESOTA.

Fischer, H. P., Shakopee.  
Lyng, J. A., Alexandria.  
Mowers, S. W., Brainerd.  
Reiter, H. W., Shakopee.

#### MISSISSIPPI.

Coker, C. M., Sharon, Madison County.  
Polkes, H. McM., Biloxi.

Jones, D. W., Hermanville.  
Mooney, J. B., Scooba.  
Payne, A. G., Greenville.  
Allen, W. W., Paris.

#### MISSOURI.

Bragg, G. G., Huntsville.  
Baker, R. W., St. Louis.  
Cline, Wilburn, Appleton City.  
Epstein, M. J., St. Louis.  
Miller, G. H., St. Peters.

#### MONTANA.

Calhoun, G. W., Butte.

#### NEBRASKA.

Carlyle, W. L., Hastings.  
Taggart, E. J., Gretna.

#### NEW HAMPSHIRE.

Dunbar, E. B., Manchester.  
Garland, W. R., Plymouth.  
Gleason, J. H., Manchester.  
Palmer, Haven, Plymouth.  
Shedd, G. H., North Conway.  
Toye, J. E., Acworth.

#### NEW JERSEY.

Cunningham, Geo., Vineland.  
Fee, E. K., Lawrenceville.  
Philhower, G. B., Nutley.  
Ridgeway, G. M., Trenton.  
Teeter, C. E., Newark.  
Webner, Fred, Newark.

#### NEW MEXICO.

Ramus, Carl, Fort Stanton.

#### NEW YORK.

Bradford, G. D., Homer.  
Brown, L., Saranac Lake.  
Coughlin, R. E., Brooklyn.  
Elsberg, C. A., New York City.  
Leitner, Geo. A., Pierpont, Rockland County.  
Roth, Henry, New York City.  
Satterwhite, P. P., New York City.  
Smith, J. R., Conewango Valley.  
Sweetman, Jr., J. T., Ballston Spa.  
Taylor, H. L., New York City.

#### NORTH CAROLINA.

Stevens, M. L., Asheville.

#### OKLAHOMA.

Bartle, Ira B., Augusta.  
Cravens, T. A., Oklahoma.  
Gamble, R. A., Alva.  
Hume, Chas. R., Anadarko.

#### OREGON.

Carl, W. E., Oregon City.  
Flanagan, W. H., Grant's Pass.  
Harris, T. W., Eugene.

May, W. J., Baker City.  
Morse, W. B., Salem.  
Parker, Wm. L., Baker City.  
Prentice, F. W., Eugene.  
Straw, Edwin E., Marshfield.  
Williamson, W. T., Salem.

#### PENNSYLVANIA.

Appel, T. B., Lancaster.  
Brown, W. H., Youngwood.  
Cocklin, C. C., Harrisburg.  
Daniell, A. W., Philadelphia.  
Hartman, F. G., Lancaster.  
Hobensack, J. R., Philadelphia.  
Houghton, C. W., Philadelphia.  
Kremer, W. H., Philadelphia.  
Jopson, J. H., Philadelphia.  
McCay, Robt. R., Trevorton.  
Siter, E. H., Philadelphia.

#### RHODE ISLAND.

Hayes, A. E., Providence.  
Monroe, W. C., Woonsocket.

#### SOUTH CAROLINA.

Knowlton, A. R., Columbia.

#### SOUTH DAKOTA.

Brown, E. L., Parkston.  
Jackson, E. B., Mound City.  
Kriesel, W. A., Milbank.

#### TENNESSEE.

Malone, G. B., Memphis.  
Wise, E. B., Chattanooga.

#### TEXAS.

Dabney, B., Bonham.  
Ferguson, E. S., Cameron.  
Hamilton, H. J., Laredo.  
Lyon, W. H., Buckholts.  
Miller, J. W., Hillsboro.  
Scarborough, A. O., Snyder.  
Shuford, F. B., Whitewright.  
Stephenson, W. O., Nevada.  
Van Nuy, J. C., Franklin.

#### VIRGINIA.

Berlin, Lewis, Norfolk.  
Martin, R. S., Stuart.  
Winfree, J. M., Richmond.

#### WASHINGTON.

Armstrong, G. S., Spokane.  
Randall, G. H., Seattle.

#### WEST VIRGINIA.

Linsz, H. P., Wheeling.

#### WISCONSIN.

Blank, H., Jackson.  
Christiansen, C. La Crosse.  
Gilm, N. N., Ashland.  
Gutsch, O. J., Sheboygan.  
Leonard, C. W., St. Cloud.  
McGovern, J. J., Milwaukee.  
Schreiner, J. K., Westby.

## Societies.

**German Medical Society (San Francisco).**—An association known as *Verein Deutscher Aerzte*, has been incorporated in San Francisco by Drs. E. Steltzner, Douglas W. Montgomery, Adolph G. Rosenthal, Emil O. Jellinek and Robert D. Cohn.

**Clinton County (Pa.) Medical Society.**—At the meeting of this Society, December 20, Dr. Saylor J. McGhee, Mill Hall, was elected president; Dr. George Green, vice-president; Dr. Robert B. Watson, Lock Haven, secretary, and Dr. Luther M. Holloway, Salona, treasurer.

**South Carolina Medical Society.**—The annual meeting and banquet of this Society were held at Charleston, December 9. Dr. John Forrest was elected president; Dr. Walter P. Porch, vice-president; Dr. Cornell, secretary, and Dr. Charles M. Rees, treasurer, all of Charleston.

**Los Angeles County (Cal.) Medical Association.**—At the annual meeting of this Association, held December 20, Dr. Jay H. Utley was elected president; Dr. Rose T. Bullard, vice-president; Dr. John C. Ferbert, treasurer, and Dr. Charles G. Stivers, secretary, all of Los Angeles.

**Medical Association of Berrien County (Mich.).**—At the annual meeting recently held, Dr. Robert Henderson, Buchanan, was elected president; Dr. Edward J. Witt, St. Joseph, vice-president; Dr. Frank A. Votey, Benton Harbor, secretary, and Dr. Frank M. Kerry, Benton Harbor, treasurer.

**Lawrence County (Pa.) Medical Association.**—The annual meeting and banquet of this Association were held at New Castle, December 13. The following officers were elected. Dr. John Foster, president; Dr. H. Elmore Zerner, vice-president, and Dr. C. F. McDowell, secretary, all of New Castle.

**Kentucky School and Hospital Medical Society.**—The faculty and instructors of the Kentucky School of Medicine, Louisville, have organized a medical society, which, at its first meeting, December 6, elected Dr. William A. Jenkins, president; Dr. Charles W. Hibbitt, vice-president, and Dr. John R. Wathen, secretary.

**Richmond (Va.) Academy of Medicine.**—At the meeting of the Academy, December 10, the following officers were elected: Dr. Lewis C. Boshier, president; Drs. William F. Mercer, Ramon D. Garcin and Moses D. Hoge, vice-presidents; Dr. Mark W. Peyser, secretary; Dr. Edward J. Moseley, treasurer, and Dr. Marvin E. Nuckols, librarian.

**Montgomery County (Ala.) Medical Association.**—At the annual meeting of this Association, held in Montgomery, December 14, Dr. Glenn Andrews was elected president; Dr. John M. Sadler, vice-president; Dr. Charles T. Pollard, secretary; Dr. Shirley Bragg, treasurer, and Dr. Robert N. Pitts, county health officer, all of Montgomery.

**Chesterfield County (Va.) Medical Association.**—The physicians of Manchester and of Chesterfield county met at Swansboro, December 11, and organized this Association with the following temporary officers: Dr. John B. Fisher, Midlothian, president, and Dr. J. C. Loving, Swansboro, secretary. The first regular meeting and election of officers will be held January 13.

**North Texas Medical Association.**—The semi-annual meeting of this Association was held in Greenville, December 10, 11 and 12. Dr. Jesse B. Shelmire, Dallas, was elected president; Dr. Jarrett T. Benbrook Rockwall, vice-president; Dr. Hugh L. Moore, Van Alstyne, secretary, and Dr. Carey A. Gray, Bonham, treasurer. Fort Worth was selected as the next place of meeting.

**South Texas Medical Association.**—The eleventh semi-annual meeting of this Association was held in Houston, December 13 and 14. Dr. Robert T. Morris, Houston, was elected president; Dr. William Keiller, Galveston, first vice-president; Dr. H. A. Barr, Beaumont, second vice-president, and Dr. D. Stuart Wier, Houston, secretary and treasurer. The next meeting will be held at Beaumont in May.

**Lamoille County (Vt.) Physicians' Association.**—A meeting of the physicians of Lamoille County was held at Morrisville, December 16, and an association organized, the object of which is to establish a uniform fee-bill. The members will have a cash customer list for those who habitually neglect to pay and any physician not receiving cash for each visit will be liable to expulsion from the association.

**Northwestern Ohio Medical Association.**—This Association held its fifty-seventh meeting at Lima, December 12 and 13. The following officers were elected: Dr. Joseph P. Baker, Findlay, president; Drs. Charles W. Moots, Delphos, and Martin S. Cramer, Ohio City, vice-presidents; Dr. Albert S. Rudy, Lima, secretary, and Dr. Theodore M. Gehrett, Deshler, assistant secretary and treasurer. The next meeting is to be held in Findlay.

**Iowa Central Medical Society.**—The semi-annual meeting of this Society was held in Marshalltown, December 10. The following officers were elected: Dr. Dorr Graves, Gilman, president; Drs. Norman E. Mighell and Benjamin F. Kierulff, Marshalltown, and Dr. Hiram H. Bay, Marshalltown, secretary and treasurer. A banquet followed and the Society adjourned to meet at Oak Bluff, the country home of Dr. Mighell near Marshalltown, in June.

**Philadelphia College of Physicians—Section on Gynecology.**—At the annual meeting of this section on December 19, Dr. George Erety Shoemaker was elected chairman for the year and Dr. John H. Girvin was re-elected clerk. Dr. Edward P. Davis read a paper on "Retroversion and Retroflexion of the Uterus"; Dr. John M. Baldy, a paper on "Adeno-Myoma of the Uterus," and Dr. Charles P. Noble, a paper on "The Technique of Amputation of the Cervix."

**Salt Lake (Utah) Medical Society.**—At the meeting of this Society, December 9, a committee consisting of Drs. Andrew J. Hosmer, Emerson F. Root, and Eugene W. Whitney was appointed to revise the constitution and by-laws to make them conform to the recommendations of the American Medical Association. The following officers were elected: Dr. J. C. Elliott King, president; Dr. Eugene W. Whitney, vice-president; Dr. Archibald A. Kerr, secretary, and Dr. Augustus C. Behle, treasurer.

**Hospital Medical Society (Rochester, N. Y.).**—At the annual meeting of this Society, December 12, the following officers were elected: Dr. George W. Goler, president; Dr. Joseph

R. Calkin, vice-president, and Dr. Charles O. Boswell, secretary-treasurer. The Society passed the following resolutions pertaining to vaccination:

WHEREAS, There is a disinclination on the part of some of the people of the city of Rochester to submit to vaccination, even in the face of a possible epidemic of smallpox, and

WHEREAS, No scientific fact is better established than the prevention of smallpox by means of vaccination repeated at proper intervals;

Resolved, That the members of the Hospital Medical Society of Rochester endorse the action of the health department of this city in recommending the vaccination of all persons not properly protected against this disease.

**Suburban Medical Society.**—An association has been formed whose object is to bring the physicians in the towns of Oak Park, Maywood, Melrose Park, Bellwood, Harlem, Berwyn, Riverside, La Grange, Elmhurst, Lombard, Franklin Park, Mount Clare, and River Forest, western suburbs of Chicago, into a closer social relation, and for the discussion of scientific questions. They will also help in establishing the new hospital, which will be opened in a short time in Maywood by the Servite Sisters. The building will be entirely remodeled and equipped with all the best medical appliances. A meeting and banquet were held at Maywood, December 27, at which officers were elected as follows: Dr. William F. Scott, Melrose Park, president; Dr. Clarence E. Hemmingway, Oak Park, vice-president; and Dr. William R. Livingston, Maywood, secretary and treasurer.

## THE WESTERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

*Eleventh Annual Meeting, held in Chicago, Dec. 18 and 19, 1901.*

*(Continued from p. 53.)*

President Dr. A. F. Jonas, Omaha, Neb., in the Chair.

### Presidential Address.—Use of the Gall-Bladder as a Suspensory Ligament for Prolapsed Liver.

DR. A. F. JONAS, Omaha, delivered the Presidential Address. He said that the liver was sometimes displaced downwards to a considerable degree; that there was usually modified function and a well-defined clinical picture belonging to this change of position. Mrs. S., aged 41, had for three years suffered from paroxysms of severe pain located in the right hepatic region. These pains, always sudden in onset, sometimes subsided in the course of one or two hours, but occasionally continued until relieved by opiates. Whether they were relieved spontaneously, or by anodynes, they were always succeeded by nausea and an aversion for food lasting for two days to a week. During the intervals she had a dragging pain in the right hypochondriac region. A year previously she had had a moderate degree of jaundice. Otherwise her history was negative. On examination her abdomen was distended and tympanitic; the abdominal walls were pendulous, soft and flabby, and covered with numerous striae, the result of child-bearing. On palpation pain on pressure was elicited over the region of the gall-bladder, but no enlargement of that viscus could be made out. A movable lump was found between the right costal arch and the iliac crest, which proved to be the right kidney. The diagnosis was biliary calculi in the gall-bladder, and movable right kidney. Cholecystotomy and nephrorrhaphy were recommended and agreed to by the patient. After the usual preliminary preparations, a vertical incision was made, beginning at a point over the median end of the ninth rib, and extending down four inches. On entering the abdominal cavity, the lower margin of the liver was three fingers' breadth below the costal arch. The liver could very easily be elevated to its normal position, but it descended very slowly when pressure upwards was released. In appearance it was normal. The gall-bladder was easily found, and several calculi could be felt through its walls. The displaced and movable kidney could be made out. The liver could be held in place by little effort, particularly when an ordinary amount of traction was made on the gall-bladder; so the question presented itself, Why not use the gall-bladder as a suspensory ligament? Accordingly, it was sutured in the uppermost part of the wound, snugly against the costal arch, the sutures passing through the gall-bladder wall, the parietal peritoneum and muscles. Before closing the peritoneal cavity, an exploration was made for the movable kidney, but it had receded to its normal position, and could not be displaced. The peritoneum was then closed, the

remaining wound sutured in the usual way, save to allow for opening the bladder. This was done and several calculi removed. A long drainage tube was introduced, and the wound was then dressed by an antiseptic, hygroscopic pad. The drainage tube was removed in one week. The wound closed at the end of four weeks. The patient was directed to wear a snugly-fitting abdominal band. Subsequently several examinations were made. On percussion, the liver had remained in its normal position and the dragging pain had disappeared. No displacement of the kidney could be made out, although she assumed several positions, straining in various ways. It was evident that the descended kidney was dependent on the descent of the liver. In this case, unfortunately, it was not ascertained whether there was associated a downward displacement of the stomach and colon. The author concluded: 1. The cause of hepatoptosis consisted in a modification of one or more of its normal supports, or an increase in the size and weight of the liver. 2. It was impossible for the liver to descend without producing a descent of the hollow abdominal viscera. 3. The utilization of the gall-bladder as a suspensory ligament to maintain and hold in its normal position a prolapsed liver, together with certain other abdominal organs, seemed practical.

#### Heart Suture.

DR. B. MERRILL RICKETTS, Cincinnati, referred to malposition, displacement and malformation of the heart, and then detailed a series of experiments which he had conducted on animals with reference to suturing the heart. He stated that there were 27 cases of suture of the heart for wounds in human beings reported up to the present time, with recovery in seven instances. In this work it was necessary to use a suture that was longer-lived than ordinary catgut, and he had employed kangaroo tendon in ligating the coronary arteries and fine-silk sutures in the walls of the heart. The sutures should be applied in systole of the heart, and not during its expansion. Certain hearts were softer than others; they broke down under the use of forceps, and forceps should not be used in this work. The indications for suturing the heart had to be worked out: but it was interesting to see how readily the chest could be opened with the right kind of forceps. He had used a kind of pruning forceps in his experimental work. He had opened the chest, reached the heart, and sutured it in forty seconds (?), and he did not think it would require much more time to do this in the human being. The aspirator should not be used for anything about the heart, because injury to the coronary arteries would often result in hemorrhage and death. The time had arrived when the surgeon should no longer hesitate to open the chest for injuries of the lung and of the heart in cases of emergency.

DR. W. W. GRANT, Denver, read a paper on "Fracture of the Metacarpal Bones, and Oblique Fracture, Simple or Compound, of the Forearm," which will appear in full in THE JOURNAL.

DR. JOHN P. LORD, Omaha, narrated in an interesting manner some of the observations that he had made during a trip in Europe.

#### Symposium on Prostatectomies.

DR. ALEXANDER HUGH FERGUSON, Chicago, read a paper on "Total Extirpation of the Prostate Gland Through a Median Incision in the Perineum." In several cases operated on by the author his results were better than he had ever secured by the suprapubic route. He stated, 1, that it was the most direct route to the organ, and that the prostate could be removed without injuring any important structure. 2. The operation was easily performed. In all those cases in which the gland had been repeatedly inflamed, it made it more difficult to operate, but not as difficult even then to remove the prostate from below as to do the suprapubic operation. 3. The removal of the gland piece by piece enabled the surgeon to work through a small opening and prevented the bruising of the surrounding parts by the finger, which was accompanied with the removal of the gland *en masse* through the perineum. 4. Hemorrhage was avoided, so long as one was careful to work within the capsule. The hemorrhage in suprapubic prostatectomy, or in the combined method, was often very alarming. On one occasion the writer had to leave pressure forceps

on blood vessels and pack the bladder tightly with gauze 24 hours. The patient narrowly escaped death from both hemorrhage and sepsis. Perineal drainage after suprapubic prostatectomy was not as complete as when the prostate was attacked from below. It was found by the writer that the danger from septicemia was not at all prominent after perineal prostatectomy, and so far had given no anxiety whatever. There was less danger of uremia. The operation took the shorter time; the anesthesia having, therefore, less effect upon the kidneys, and a minimum opportunity for sepsis made it easier for the kidneys to perform their functions. The suprapubic operation was accompanied with far more shock than the author had found following perineal prostatectomy.

DR. LEWIS SCHOOLER, Des Moines, Iowa, read a paper on the "Symptoms, Signs, Diagnosis, Prognosis and Palliative Treatment of Hypertrophy of the Prostate." The palliative treatment was divided into massage, aspiration, catheterization, dilatation, and cystotomy. In considering all of the above methods, none were intended to be radical; none were calculated to remove the cause. All were intended to partially, at least, restore functional activity and to produce results sufficiently satisfactory to prevent the need of more radical procedures, and until within the last five years they were the best that the profession possessed. The dissatisfaction with them was clearly shown by the constant aim to discover something that would give better results. In a few cases they had served the purpose well, and in the future would be resorted to in very few selected cases. But the better knowledge of the anatomy of the prostate gland and its pathology called for an advance in therapeutic resources that did something more than to secure relief with a constant menace to the life of patients through infection, as well as a method that did not require eternal vigilance and a knowledge of the fact that the life of the individual depended upon the mechanics of artificial urination.

DR. A. C. BERNAYS, St. Louis, Mo., dealt with the "Pathology and Etiology of Prostatic Hypertrophy and Suprapubic Drainage as a Method of Treatment." Suprapubic cystotomy was an operation which found its application in stone in the bladder, tumors and growths, hypertrophy of the prostate, foreign bodies, exploration of the bladder, and drainage of the bladder. It was a recognized and successful method of treatment in all of these conditions. The technique varied with the object in view. Some ten years ago the speaker had the notion that suprapubic drainage would cure prostatic hypertrophy. He reasoned that by the drain he could give complete physiologic and mechanical rest to the bladder; he could prevent the unrest due to the alternate filling and emptying of that viscus. He had hoped that the hypertrophied prostate under the influence of rest would undergo absorption and atrophy, and that a decrease in size, which might be permanent, would take place. In this latter hope he was disappointed. In all cases of hypertrophy of the prostate in which he made free permanent drainage for from three to ten weeks, the urine became normal in color, the cystitis was much improved, and in some cases entirely cured. He was convinced that as a radical cure of prostatic hypertrophy the suprapubic drainage was a failure. He spoke of hypertrophy of the prostate as a form of neoplasm or tumor. It was either a diffuse myomatous hypertrophy, or it was a localized formation of nodular myomata except in rare instances. Myoma could not be made to disappear by castration, either in men or in women, nor could it be made to do so by giving the parts in which the myomata were located physiologic and mechanical rest by means of the suprapubic drainage. His training and feelings were so much opposed to operations in the dark that the Bottini and even the popular internal urethrotomy could receive no support from him.

DR. C. H. MAYO, Rochester, Minn., discussed "Suprapubic Prostatectomy." Prostatic surgery had developed from suprapubic cystotomy. Statistics should only be considered in a general way, as representing the developing stage of prostatic surgery. One-half of the enlarged prostates could be reached either from above or below equally well, one-fourth better from above, and one-fourth better from below, and a few would

require a combined operation. The method of operation was influenced by the condition of the gland, and by other known and oftentimes unknown conditions. The lateral lobes were glandular and encapsulated; the middle might be glandular and encapsulated, or a muscular bar, or hypertrophy of mucous glands and bladder tissue. Of known conditions which influenced one's choice, the fleshy individual with thick perineum, long prostatic urethra, and high-lying prostate was one for suprapubic or combined operation. Large dilated bladders were easily reached from above, and small contracted bladders more easily from below. Those with stone present and enlarged prostate were best made from above. Of unknown conditions which influenced one's choice, he had cases of symptomatic stone not found by search, and emergency operations made in the country. These were the cases in which the suprapubic incision was the most satisfactory. Those with cystitis and old or acute secondary changes in the testes would often improve after castration. There was still a large class of prostatic sufferers in whom there were no symptoms of stone, little or no cystitis, and short perineal distance in which a perineal operation was unquestionably the better method. The ease of operation, perfect drainage and earlier recovery in chosen cases no doubt justified this choice. The special retractors of Syms and Ferguson simplified the accessibility of the gland from below, and it was quite possible from present indications that this method would be developed into the operation of the future by making earlier diagnosis of conditions and operating before the patients reached the stage of necessary suprapubic incision. Before suprapubic operation, a hypodermic of morphia was given to reduce the amount of the anesthetic. Usually chloroform was indicated, but ether was preferred. The Trendelenburg position with air inflation of bladder and finger enucleation of enlargements after incising the capsule. Suprapubic drainage should be established by closing the bladder over the tube by Witzel's method.

DR. LOUIS E. SCHMIDT, Chicago, read a paper on the "Indications and Limitations for the Bottini Operation." After discussing at length the indications and limitations of this operation, he concludes that good results of the Bottini operation will depend on the correct selection of cases, the proper technique of the operation and proper after-care, and the immediate correction of errors or mishaps.

#### How Shall We Treat Sepsis Following Labor and Abortion?

DR. W. O. HENRY, Omaha, in a paper on this subject, took the ground that it was important to remember that sometimes malarial and other fevers followed closely upon abortion and labor, and all such cases should be carefully distinguished from true puerperal sepsis; but having once fully determined that infection has really occurred along the genital tract, only one line of treatment was justifiable in the present state of our knowledge. Although he admitted the different varieties of infection, yet, since it was both unsafe and impractical at the present time to wait for bacteriologic examination, and since, further, the treatment he recommended was safe, practical, curative, and within the reach of every physician, he insisted upon its universal adoption. After giving somewhat elaborately the reasons for his belief, he summarized as follows: 1. Remove early with the finger, sharp curette and flushing, all debris, decidua, blood clots, and sloughing tissue which may be infected, from the uterus and from all raw surfaces in the cervix, vagina and vulva. 2. Dry all of these raw surfaces and freely apply to them 95 per cent. carbolic acid, washing away the surplus acid with sterile water. 3. Unless hemorrhage requires, leave no tubes nor packing of any kind in either the vagina or uterus. 4. Have simply carbolized 2 per cent. vaginal douche used twice a day thereafter. 5. Open the bowels freely with calomel, one-half grain every hour for four hours, then follow with Rochelle salts, until sufficient action has occurred. 6. Give quinin, three grains every four hours, followed by tincture of chlorid of iron, 15 drops, in water. 7. Give good nourishment with milk, eggs, and stimulants every four hours. 8. Let this be the routine early treat-

ment, and hysterectomy will be rarely required. 9. When fixation of uterus occurs, and infiltration takes place in Douglas' cul-de-sac or the broad ligaments, or when the tubes or ovaries fill with pus in acute cases, open promptly and drain through the vagina. 10. If multiple abscesses occur in the uterine wall, or the walls become badly infected, or, if necessary, to get perfect drainage for a badly infected pelvic cavity, remove the uterus and all else necessary by the vaginal route. The abdominal route is dangerous in all acute cases, and is seldom, if ever, justifiable.

#### New Method of Anchoring the Kidney.

DR. BYRON B. DAVIS, Omaha, said that this method can best be explained by giving a report of the only operation yet done by it. A. J., unmarried female, aged 21 years, had frequent gastric crises, and a good deal of constant lumbar pain, on right side especially. Had lost 25 pounds in weight during the past year, and was very anxious for relief. On examination the right kidney was found freely movable, falling so low that the upper pole could be felt on bimanual examination. The left kidney was also somewhat movable. Patient entered hospital Nov. 9, 1901, for operation on right side, which was done November 11. The incision extended from the lower rib to near the crest of the ilium, a hand's breadth to the right of the spinous processes of the vertebræ. The fatty capsule was reached just anterior to the outer border of the quadratus lumborum, and was opened and a large part of it trimmed away. The kidney was pushed into place by a cylindrical pad placed under the abdomen. When the kidney was well exposed, an incision was made through the proper capsule from one process below the upper pole to a point 2 cm. above the lower pole. This incision was placed vertically on the posterior surface near the convex border. The capsule was stripped loose from the kidney substance from a distance of three-fourths inch anteriorly and posteriorly to the incision of the capsule. From the upper and lower extremities of the vertical incision a perpendicular incision three-fourths inch long was made through the capsule, this giving two flaps of capsule three-fourths inch wide by about two and one-half inches long. Next a strip the thickness of one's little finger of the other border of the quadratus lumborum muscle was split off from the remainder of the muscle, the fibers being separated by the handle of the scalpel. This separation extended from the muscular attachment to the twelfth rib downward for two and one-half inches, or the slit in the muscle was made as long as the length of the capsular flaps before described. Next, an artery forceps was passed through the slit in the muscle, made to grasp the free border of the posterior flap of the kidney capsule and then withdrawn, bringing the flap of the kidney capsule through the slit in the muscle. The two capsular flaps were next brought together over the bundle of muscular fibers, thus isolated from the border of the quadratus lumborum, and stitched together with a running suture of fine chromic catgut, the needle being allowed to penetrate the muscular bundle at two or three places. The lumbar wound was next closed by tier sutures of catgut, the skin wound being closed with horsehair. Aside from a slight infection, the wound did well. Patient was allowed up on the 22d day. The kidney thus far was in place, and the patient relieved of her former symptoms, although it was too early to predict anything of the final result. This method was reported because it represented a new principle in treatment.

#### Intestinal Obstruction from Meckel's Diverticulum.

DR. A. E. HALSTEAD, Chicago, presented the following summary of all cases in the literature that were accessible to him: Total number of cases reviewed, 72; males, 45; females, 17; sex noted in only 62; result noted in 65; deaths, 44; recoveries, 21; percentage of mortality, 67.6; percentage of recovery, 32.4; cases operated on, 55; death in cases operated on, 27; no operation in 17; percentages of death in cases operated on, 49.0+; attachment or non-attachment of diverticulum or diverticular ligament, mentioned in 66; point of attachment noted in 44; to mesentery in 21; to umbilicus in 14; not determined in 3; diverticulum attached, 47; and diverticulum free, 19.

### Grave Abdominal Injuries Without External Evidences of Traumatism.

DR. R. HARVEY REED, Rock Springs, Wyo., read a paper in which he discussed this subject. From reading the literature, together with his own experience, he was led to the conclusion that it was the surgeon's duty to make an exploratory incision in all cases where there was grave doubt as to the real nature of an injury, and particularly so when the constitutional symptoms pointed to a condition more serious than was indicated by either the subjective or objective symptoms, provided the physical condition of the patient was such as to warrant such an operative procedure.

### Immediate Effects of Intestinal Exposure.

DR. A. W. ABBOTT, Minneapolis, detailed a great many experiments on animals with a view to determining the immediate effects of intestinal exposure. From his experimental work he concluded that in operations where the intestines were exposed, the loss of water was unimportant, except in so far as it influenced the loss of heat and the drying of the surface; that the loss of heat was very important, as it temporarily placed the temperature of the intestines below the safety line of vital action, and secondarily the heat of the whole body below that which should be continuously maintained; that the drying of the peritoneum was so decided that it must disturb to some extent the anatomic relations, and the resisting and recuperating power of that membrane; that the loss of heat and the drying process must suspend for an undetermined period some of the physiologic functions of the peritoneum, and influence, to a degree as yet unknown, pathologic conditions. These conclusions the modern surgeon had reached clinically, in a general way, as shown by a short incision, protection pads, a minimum exposure of the peritoneum, and short-time operations. The writer believed that the exposure of the peritoneum should be the subject of a more critical study, and that this should be supplemented by extended experiments on the later effects, especially in their relation to peritonitis and adhesions.

### Our Hospitals.

DR. H. D. NILES, Salt Lake City, spoke on this subject. He said it was very evident to the minds of physicians familiar with the situation that the methods and management that had served hospitals so well when their purpose was limited to the care of the sick within their walls, would not suffice if the hospitals were to meet present needs and fulfill their possibilities as a great system of scientific institutions distributed throughout this country, where not only the favored few but the whole profession with all the sick entrusted to their care might feel the results and participate in the benefits. So long as a hospital measured its own usefulness by the number of patients treated, the standing of each member of the staff would be estimated largely by the size of his personal following; and the commercial spirit would rule both the institution and the individual to the exclusion or great detriment of scientific work. If the profession was ever to secure a voice, it should formulate and adopt a business code that should not only meet the highest requirements of the ethics of the profession, but at the same time command the respect and win the confidence and support of the 20th century public. The object of the paper was to arouse, if possible, a more active interest in an institution that promised with the aid of medical men to become one of the most influential elements in the medical world.

### Surgery of Spina Bifida.

DR. VAN BUREN KNOTT, Sioux City, Iowa, discussed the varieties of spina bifida, the clinical features, diagnosis, prognosis and treatment. After reporting four cases, he drew the following conclusions: "1. Owing to the distressing nature of the affection, the high mortality should not prevent attempts at surgical relief. 2. Meningoceles, meningocele, and syringomyelocoeles may be considerably benefited by operation. 3. The improvement in function can not with certainty be estimated before operation, and pronounced evidences of nervous disturbance are not a contra-indication to excision. 4. Asepsis is absolutely essential and, although difficult to secure, may be maintained by exercising extreme care. 5. The plan of hav-

ing the suture lines of the meninges and the overlying tissues on different planes will in the majority of instances prevent leakage of cerebrospinal fluid. 6. The suggestion of Pearson to prevent the escape of this fluid during a prolonged operation by stuffing the canal with gauze is valuable. 7. Large bony defects may be effectually closed by muscle much easier than by osteoplastic methods. 8. It is not necessary to keep the child off its back during the healing of the wound, as is frequently advised. 9. Children with hydrocephalus accompanying spina bifida should not be subjected to operation."

Other papers were read as follows: "Two Cases of Cysts of the Broad Ligament Complicated with Myxoma," by Dr. Edward Hornbrook, of Cherokee, Iowa; "Diffuse Sarcoma of the Uterus," by Dr. D. S. Fairchild, of Clinton, Iowa; "New Operation for Wandering Kidney," by Dr. E. Wyllys Andrews, of Chicago; "The Operative Relief of Impaired Function of the Elbow-Joint Due to Faulty Re-attachment of a Separated Internal Humeral Epicondyle," by Dr. G. G. Cottam, of Rock Rapids, Iowa.

The following officers were elected for the ensuing year: President, Dr. James E. Moore, Minneapolis, Minn.; 1st vice-president, Dr. J. R. Hollowbush, Rock Island, Ill.; 2d vice-president, Dr. W. W. Grant, Denver, Colorado; secretary-treasurer, Dr. George H. Simmons, Chicago.

St. Joseph, Mo., was selected as the place for holding the next annual meeting; time, December 29 and 30, 1902.

## Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

### PRESCRIPTION WRITING, VIII.

(Continued from page 59.)

#### Incompatibilities.

Prescriptions may be regarded as incompatible when they include drugs which oppose each other in their physiologic action, or when an ingredient, administered in a liquid form is insoluble in the mixture containing it, and when an ingredient is thrown out of solution by its admixture with other liquids. However, substances which are insoluble in the ordinary solvents may not be regarded as incompatible unless an even distribution can not be made through the menstruum or vehicle. A prescription is also incompatible when by combining two or more ingredients a chemical change takes place.

Incompatibilities, therefore, may arise: 1, therapeutically; 2, pharmaceutically; and 3, chemically.

#### PHYSIOLOGIC INCOMPATIBILITY.

Therapeutic incompatibilities take place when drugs are prescribed together which are opposite in their action upon certain parts of the system. To avoid such incompatibilities it behooves the practitioner to exercise care unless such actions are desired. The druggist is not bound to checkmate such combinations, because it is not unusual for such prescriptions to be written by the physician in order to accomplish a certain purpose. For example, in some conditions of the pulmonary circuit where there is marked congestion, perhaps from pneumonia or chronic endocarditis in some form, it may be desired from the nature of the condition to prescribe digitalis, but to avoid the high arterial tension produced by this drug, some preparation may be combined with it or given in alternate doses with the digitalis to relieve the arterial tension by producing an opposite action upon the coats of the vessel.

For such purposes the nitrites may be given. Consequently, a prescription containing such a combination as the foregoing would be regarded as therapeutically incompatible, and yet with a proper knowledge of their action, incomparable advantage sometimes may be accomplished by that method.

The prescribing of aloes with the iron preparations is of service in preventing the constipating effects of the iron; these

drugs are frequently administered together in the form of pilula aloes et ferri. It is common to include extract of hyoscyamus or extract of belladonna in laxative or purgative pills to prevent them from griping by regulating peristalsis. Caffein citrate may be combined with acetanilid in such quantities as to counteract its depressant effects on the heart. Likewise in certain individual drugs there are found principles which are antagonistic to one another in their action; in jaborandi, opium, and rhubarb, for example, there are certain antagonistic principles which exist in such proportions that one drug acts as a corrective to the other and not as a neutralizer. Morphin when given hypodermically is guarded in its action upon the heart and respiratory centers by atropin combined with it.

#### PHYSICAL OR PHARMACEUTICAL INCOMPATIBILITY.

A prescription is pharmaceutically incompatible when the combined ingredients composing it do not form a clear solution; however, no chemical change takes place. For examples, oily preparations and insoluble powders are pharmaceutically incompatible with water. A combination of acids and glycyrrhiza will cause the active principle glycyrrhizin to be precipitated.

Chloral hydrate will not mix with alcoholic solutions, but separates to the top of the mixture and unless the mixture is properly shaken before being administered the first few doses may contain an excess of chloral.

So in prescribing fluid extracts in aqueous solutions, their constituents, such as gums, resins, albumins, or mucilages, may be separated and thrown out of solution.

The sugar in syrups becomes crystallized if alcohol or alcoholic preparations are used in the combination.

Volatile oils should not be prescribed with aqueous solutions in greater proportion than one drop of the oil to an ounce of water in order to avoid physical incompatibility.

Saturated solutions of a drug should not be prescribed with aromatic aqueous solutions, as the volatile principle in the water will be liberated and the mixture will become cloudy. However, the taste of the bromids or iodids, in smaller quantities, is masked better when prescribed with the aromatic waters such as aqua menthae piperitæ or aqua menthae viridis than by the syrups.

Fluid extracts and tinctures containing resinous principles should not be prescribed with water, for the resins which are held in solution by the alcohol in the tinctures are precipitated by weakening that menstruum; under such circumstances if it is desired to use aqueous rather than alcoholic solutions, resinous principles may be suspended in an emulsion by adding mucilage of acacia, or tragacanth, which is sometimes used in its stead because its preparations preserve better.

(To be continued.)

#### Itching from Frost Bites (Chilblains).

Tincture of iodine lightly painted over the affected parts will, in the majority of cases, relieve the itching. As a temporary relief, immersing the parts involved in a mustard bath should be resorted to. The following combinations locally applied are very highly recommended in such cases:

R. Pulv. camphoræ ..... 3i 3/75  
Vasellini ..... 3iv 15

M. Sig.: Rub in well, night and morning; or:

R. Ichthyol ..... 5/62  
Pulv. camphoræ ..... 3i 3/75  
Lani ..... 3ss 1/87  
Vasellini ..... 3iv 15

M. Sig.: Apply locally night and morning and cover with cotton wool.

An application containing cocain may be used in case none of the foregoing will control the subjective symptoms. It may be combined as follows:

R. Cocainæ hydrochloratis ..... gr. iii to v 20-30  
Bismuthi subnitratis ..... 3ss 1/87  
Vasellini ..... 3ss 15

M. Sig.: Apply locally night and morning.

#### To Prevent Chordee.

Dalton, in *Edinburgh Med. Jour.*, recommends the following as an injection:

R. Sol. morphinæ hydrochlor. .... m. xv 1  
Cocainæ hydrochlor. .... gr. ss 03  
Aquæ q. s. ad. .... 3ii 7/5

M. Sig.: Inject into the urethra and retain for five minutes before retiring.

As an injection for residual gleet he states that astringents are required (after the irrigation treatment) when there is a thin glycerin-like discharge. The following combination is employed by him:

R. Zinci sulphatis ..... gr. ss-gr. iii 03-20  
Plumbi subacetatis, 3ā ..... m. x-xxx 66-2  
Tinct. catechu ..... 3ss-3i 2-4  
Glycerini ..... 3i 30  
Aquæ q. s. ad. .... 3i 30

M. Sig.: Use as an injection.

#### Treatment of Catarrhal Conjunctivitis.

The following is recommended by Terrier:

R. Ammon. chloridi ..... gr. i 06  
Zinci sulphatis ..... gr. iiss 15  
Camphoræ ..... gr. 1/6 01  
Aq. destil. .... 3iiss 13/12

M. Sig.: Instill into the eye once or twice daily.

#### Formula for Chafing.

Dr. R. B. Elderice recommends the following in treatment of chafing under the arms and in the groins of infants:

R. Ichthyol ..... 3i 3/75  
Tr. benzoini comp. .... 3ii 60  
Acidi borici, 3ā ..... 3i 3/75  
Petrolati ..... 3ii 60

M. Sig.: Apply frequently through the day.

#### Ether Compresses in Strangulated Hernia.

George, in *Jour. des Pract.*, reports two cases of strangulated hernia in which he could produce no effects by taxis. He saturated compresses with ether and applied them to the parts and at the same time produced moderate taxis. After the compresses were kept in position for several hours reduction was accomplished without much difficulty.—*Amer. Med.*

#### Local Treatment in Erysipelas.

J. B. Sloan, Detroit, recommends the following in treatment of erysipelas:

R. Tinct. opii ..... 3iv 15  
Ext. aconiti flu. .... 3ii 7/5  
Ext. belladonnæ ..... 3iv 15  
Ext. veratri viridis flu. .... 3iii 11/25  
Ichthyol q. s. ad. .... 3iv 120

M. Sig.: Apply every three hours.

#### Treatment of Dysphonia (Hoarseness).

The voice should be used as little as possible. The cause should be ascertained and removed if possible and the following gargle can be employed in case of emergency when it is desired to use the voice in singing or speaking.

R. Acidi tannici ..... gr. xl 2/66  
Boroglycerin ..... 3iiss 6  
Tinct. capsici ..... m. xx 1/30  
Infusi rosæ q. s. ad. .... 3v 160

M. Sig.: Use frequently as a gargle.

#### Tinea Tonsurans (Barber's Itch).

The following combination is a serviceable one for the cure of barber's itch:

R. Ichthyol ..... gr. xxxv 2/33  
Sulphuris præcip. .... 3ii 7/50  
Vasellini ..... 3iiss 45

M. Sig.: Apply locally at night.

#### Employment of Bitters in Anorexia.

According to Huchard, as stated in *Amer. Med.*, the drinking of water before meals increases the hydrochloric acid in the gastric secretions more than does the use of bitters, and as

bitters often cause the sensation of hunger he seldom prescribes them. The use of small quantities of alkaline salts causes marked increase of gastric secretions. The following may be used:

R. Sodii phos. (neutral) .....5iii 11|25  
Sodi bicarb. ....5iiss 5|62

M. ft. cachets No. 1. Sig.: One cachet, a half-hour before each meal.

To increase digestion the following should be given after meals:

R. Acidi hydrochlorici .....m. viii |50  
Elix. curacao .....3ii 60  
Aq. destil. ....Oj 480

M. Sig.: A wineglassful after each meal.

## Medicolegal.

### Duty of Company Assuming Charge of Injured Person.

—The Supreme Court of Mississippi holds, in *Dyche vs. Vicksburg, Shreveport and Pacific Railroad Company*, that the company, having assumed charge of an injured person, although it was not liable for his original injury, was charged with the duty of common humanity. It was to be charged with no higher degree of duty than that of ordinary humanity, but the jury must settle that on the facts.

### Treatment of Cases by Secretary of Board of Health.—

—The Supreme Court of Tennessee says, in disposing of the case of *Knox vs. the Mayor and Aldermen of the City of Knoxville*, that the Court of Chancery Appeals held, on the proof, that the complainant was not employed to render the professional services in the treatment of smallpox patients during the prevalence of an epidemic for which he sought to recover payment, and that, so far as the city was concerned, they were rendered gratuitously and wholly without authority to bind the mayor and aldermen. It says, too, that the court found there was nothing to show that the city authorities accepted his services, or could in any way have prevented them; and that the city was given no notice that he was rendering the services charged for, and was relying on the city for pay. The fact, it goes on to state, was that at the time he claimed to have rendered these services he was in the employment of the city at a salary of \$300 per annum, as secretary of the municipal board of health. The city authorities were well warranted in believing that he was rendering these services in connection with his office. Wherefore, the Supreme Court holds, under the facts found, and the law governing the case, the city was not liable for the services. Moreover, it holds that the city physician had no authority to employ him to perform such services at an extra compensation, nor any authority to incur any liability against the city.

### Court of Appeals on "Oxydonor" Patent.—

The United States Circuit Court of Appeals, Eighth Circuit, in *Mahler vs. Animarium Company*, expresses the opinion that the patented device covered by the Sanche patent, No. 587,237, of July 27, 1897, considered by itself, and apart from the force, if any, that is thereby utilized, contains no features of novelty entitling it to a patent; it being nothing more than a wire connecting two metal pads. It is furthermore of the opinion that if what is ordinarily termed an "electric current" is generated or occasioned by the attachment of the wire to two objects of a different temperature or different polarity, and if the curative effect of the device when applied to a patient is due to a slight electric force or energy thereby generated, then the device is wanting in patentable novelty. There is nothing new, it says, in the idea of using electric energy to heal disease, although it may not be well enough proven to be accepted as an established scientific truth that electricity does effect cures. Then, the court says that it has been forced to conclude, after a careful study of the specification in the patent, that the theory enunciated by the inventor, that most diseases are "due to a disturbance of the electrical equilibrium of the body," is a mere pretense; that is to say, a theory not entertained by the

inventor in good faith, but put forward as an imaginary hypothesis merely for the purpose of obtaining a patent on a very simple contrivance, which was not patentable unless the claim was reinforced by some such pretended discovery. Likewise, it also concludes that the statement in the specification to the effect that the inventor does not by means of his device make use of "dynamic currents," but relies on some other mysterious and unexplained property of electricity to effect cures, is a statement which rests upon no substantial foundation, and was most likely inserted in the specification for the purpose of forestalling objections to the granting of a patent which would probably have been made if it had been conceded by the inventor that an electric current was generated and flowed along the connecting wire, to which the healing effect of the device might be attributable. For these and other reasons, the court holds that the patent in suit does not describe or cover a patentable device, and that it ought not to have been granted.

**Ratification of Employment of Physician.**—The case of *Steiner vs. Polk County, Oregon*, was brought by a physician and surgeon to recover \$125 for professional services rendered to a minor who was severely injured by a gunshot wound necessitating the amputation of his leg, but who was unable to provide himself with proper care or attention, and had no relatives or friends able or willing to help him. The case was of urgent necessity, and, as the County Court was not in session, the judge thereof advised and recommended that the patient be taken to a certain hospital for treatment, and requested this physician to give him necessary medical attention, and present his bill to the County Court; saying that he did not know what the court would do, but was satisfied it would allow a reasonable compensation for his services. In pursuance of this arrangement, the physician had the patient removed to the hospital, provided with care and attention, and rendered him such professional services as were necessary. The County Court thereafter allowed and paid bills for the patient's care, board, and hospital charges, but upon the presentation of the physician's claim for professional services ordered that \$41.75 thereof be allowed, and that the sum of \$83.25 be disallowed. This action the physician refused to abide by, and obtained a judgment in his favor, in this case, which the Supreme Court of Oregon has affirmed. It says that there was no controversy in this case as to the value of the services rendered, the sole defense being that the county was not liable, because there never was any contract binding upon it to pay for such services. But the Supreme Court considers it immaterial whether the county judge had authority in the first instance to make a contract with the physician or not, because it holds that, after the contract or arrangement had been made and the services rendered, the County Court, in effect, ratified and approved the same. It paid the bills for all incidental expenses incurred by the physician, and when his claim for services was presented and under consideration it did not deny liability or repudiate the contract, but allowed thereon the sum of \$41.75; thus, in effect, recognizing its validity, objecting thereto only on the sole ground that the amount charged was unreasonable. There could be no question, the Supreme Court declares, if the defendant were an individual or private corporation, that such an act would amount to a ratification, and it thinks the same result follows in the case of a public corporation.

## AMERICAN.

1. 2. 3. **Laceration of the Perineum.**—Twitchell says that it is common to think of a tear as a split from the fourchette backward. This occurs in slight tears but not often in serious ones. Usually the perineum gives way at once. When a child is to be born, this oval opening is not stretched as by an entering wedge, but by having the lower end pushed away from the upper. If in swinging the head, as it extends, it slides on the perineum, the space between the pubes and the fourchette will increase; if it does not slide, the opening will not increase and the perineum will follow the motion of the head, causing decided stretching, but not enlarging the opening. Hence the importance of keeping in the vagina a lubricant which aids it. The natural lubricant is the best and should not be lessened by douches, too frequent examinations, etc. Artificial lubricants do not replace the natural one. Delaying a precipitate labor by chloroform will save the perineum in some cases, and in protracted labor the use of forceps and extraction between pain may be sufficient. The principal thing is to keep the head from coming through too quickly. Three elements are to be considered in the prevention of laceration: 1. The head should be presented in its smallest diameter. The bladder and rectum should be always empty so as not to take up any space. The patient must refrain from the use of voluntary movement at this time. The attendant should retard a too perceptible progress of the labor. In many cases the modified Walcher position is of value in protecting the perineum by its relaxing effect and permitting easy and constant observation.

Walker believes in anesthesia for preventing voluntary muscular contraction and to lessen involuntary ones, and it may be necessary to carry the anesthesia to a surgical degree during

the last few minutes. Many perineae are torn after the expulsion of the cranium by too sudden extension of the head. He avoids this by keeping the head flexed completely until its largest diameter has escaped under the arch. The posterior shoulder should always be looked after, by causing lateral flexion of the trunk.

The cause of laceration, according to Andrews, is the continuance of the powerful force after its necessity has been passed. The most frequent direct cause is imperfect flexion of the fetal head, and decided disproportion between the presenting part and the outlet, or where faulty mechanism is present, and the presenting part is pushed too far posteriorly, and not allowed to emerge safely under the pubic arch. Finally, old lacerations are liable to induce severer ones. The whole subject of prevention may be summed up: 1. Patiently and persistently endeavoring to bring the longest diameter of the presenting part in relation with the longest diameter of the outlet. 2. Securing perfect dilatation of the soft parts at the outlet. The abdominal muscles play by far the most important part in the expulsion of the head and it is an advantage that we have them under our control. He believes in the use of chloroform in these cases. The advice to support the perineum is accountable for many lacerations of the perineum; it is not the perineum which needs support, but the head, until the muscle structures have been stretched. Position is very important; he thinks the lateral better than the dorsal. The parts should be accessible to sight and touch. Forceps in certain cases are of value; for the correction of certain errors in mechanism, overflexion or overextension, they are the best means available. Episiotomy is not advised and is considered ineffective. Lacerations by the shoulders are less excusable than those by the head. If undue haste is avoided and the head lifted upward one shoulder will be behind the symphysis, while the other is safely borne over the perineum.

4. **Rectal Valves.**—Bodenhamer reviews the anatomy and its literature in regard to the rectal valves and believes that he has disproved their existence.

12.—See also ¶26 below.

13. **Brain Abscess.**—Jack reports a case of brain abscess operated upon successfully with perfect recovery.

14. **Aphasia.**—Walton gives the details of a careful examination of the same case and finds that the form partakes of Bastian's amnesia verbalis, resulting from lowered activity of the auditory word center as well as that of commissural amnesia resulting from defective transmission of stimuli to and from that center. It includes Wernicke's conduction aphasia, which denotes a break in the connection between the auditory and kinesthetic center, and is itself included in the comprehensive sensory aphasia of Oppenheim and others and the auditory sensory aphasia of Collins. That the auditory word center was not entirely destroyed was shown by the fact that the patient understood ordinary commands, but that its function was impaired was shown by the patient's inability to understand more unusual words, also his inability to produce spontaneously in conversation the desired word except of the simplest variety. It is probable, that the auditory word center itself was not involved in the encephalitis, but the moderate word deafness was due to impaired conduction of the afferent fibers conveying stimuli to that center "(subcortical sensory aphasia, pure sensory aphasia of Dejerine). The result of such lesion is obviously identical as far as understanding the speech of others is concerned. The diagnostic feature consists in the fact that if the afferent fibers only are affected the patient can still speak spontaneously, because the centers and connecting fibers necessary for this function are intact. It might be inferred, then, that in our case the auditory center was affected because he could not use spontaneous speech perfectly, but here we are met by the probability that the fibers connecting the temporal lobe with Broca's convolution were interrupted, a lesion in itself sufficient to prevent spontaneous speech. This study well illustrates our limitations in the attempt to establish the degree in which the different elements of the speech mechanism are affected in a given case. At the same time, it illustrates

the accuracy with which we may differentiate the sensory from the motor form of aphasia. It seems probable that the fibers connecting the visual with the auditory center were interrupted, for he found difficulty in reading aloud, and though he could recognize an object he could not recall its name. The fibers passing in the opposite direction were doubtless also interrupted, for he could not write difficult words from dictation. That the fibers passing from the auditory area to Broca's convolution were probably impaired is shown by the fact that though he could hear and, to a certain extent, interpret from hearing, he could not talk correctly (paraphasia)." There is no reason to think that Broca's convolution was invaded and the case supports the views of Wernicke, Broca, Trousseau, and others, that there is no writing center in the sense of a center in which are stored up the kinesthetic memories of written words. The inability to write in this patient was absolutely coincident with his inability to talk. The case is discussed elaborately. Finally, two months after the examination the patient again presented himself and no defect of speech could be elicited whatever. The only trouble he had was in the use of one or two words. Recovery seemed complete.

15. **Congenital Elevation of the Shoulder.**—Goldthwait and Painter report two cases, one probably due to imperfect development of the muscular structures, analogous to congenital torticollis in which the sterno-cleido-mastoid muscle is imperfectly developed and probably due to injury at the time of birth. In the other case the position of the shoulder was associated with embryonal conditions, there being a distinct articulation between the upper angle of the scapula and the seventh vertebra. Operation on both of the cases produced a certain degree of relief.

20. **Yellow Fever.**—Souchon argues against the statement of Doty that five days from an infected port is sufficient to eliminate the danger of yellow fever introduction and enable us to dispense with quarantine. He reports a number of cases where a longer period elapsed before the outbreak of the disease.

22. **The Typhoid Spine.**—Taylor reports a case and discusses the condition. He thinks that it is hardly possible that it can be solely spinal irritation and that there is really a definite pronounced affection of the tissues in some cases at least. Deformity would seem to be present in these structural cases but absent in purely neurotic ones.

24. **The Middle Turbinate and Chronic Diseases.**—Baker argues for the relation of the morbid conditions of the turbinate to other diseases and describes three classes of cases where they may occur and where its removal is indicated: 1. Where it is associated with polypoid growths which the most careful extirpation with snare, curette, caustic, or cautery will not cure until the turbinate is removed either in whole or in part. The second indication is sinus occlusion by a swollen membrane, which is not polypoid and does not respond to other recognized means of treatment by cleansing and disinfection. He knows of two patients who died from cerebral inflammation that he knows could have been saved by early removal of the turbinate so as to permit free drainage of the infected sinuses. The third indication is fetid crusting of the discharges in the upper portion of the nasal chambers in non-specific cases. The fifth condition is where the turbinate lies in close proximity to the more sensitive area of mucous membrane and by contact causes various nervous disturbances such as persistent sneezing, cough, asthma, headache, eye reflexes, vertigo, tinnitus, and even chorea and epilepsy which he claims can be caused this way and relieved by this operation. The sixth class is that of vasomotor rhinitis running along throughout the year. He does not claim that removal of the turbinate will cure such cases alone, but it will greatly shorten the period of suffering and give relief. The method of operating is the following: After thorough cleansing, using cocaine on a cotton applicator and leaving pledgets for ten minutes between the bone and outer walls, then applying suprarenal extract or adrenalin, the attachment of the bone to the lateral wall is then severed with the Holmes middle turbinate scissors. If the rear portion is out of reach of the scissors it is cut off

with the snare. The cavity is then packed with iodoform gauze, usually removed on the following day and frequent cleansing with borax solution is done by the patient until healing is complete.

**25. Functional Amblyopia.**—The conclusions of Pearse's article are: Our knowledge of the manifold manifestations of the disease, hysteria, in every structure of the body will not permit us to say positively that the retinal elements, the conducting channels of visual sensation, or the visual centers themselves, are free from the influence of this disease. The effect upon the visual apparatus of fright, shock, emotion, mental exhaustion, overexertion, etc., is essentially the same as in hysteria, and whether the sympathetic is concerned in this action is yet a question. In view of the known sphere of action of the sympathetic and of the many cases observed which present the same conditions in the vessels of the fundus which the influence of the sympathetic produces elsewhere in the body, if the sympathetic does not influence the fundus-vessels, what does? Until a more plausible source of influence is positively demonstrated, we can not do better than accept this explanation, which is far removed from a theory.

**26. Surgical Tendencies.**—Fitz's article is largely skeptical as regards the value of many surgical operations. He gives a table of the results of exploratory laparotomies in the Massachusetts General Hospital from 1890 to 1900, making a rather poor showing. He does not think that the surgery of malignant tumors is encouraging from the statistics, though a prolongation of life and relief of symptoms may be obtained in some cases. He analyzes the cases that have been operated on in the Hospital and the results rather justify his pessimistic views. Intracranial tumors form another series than have been operated on and from 15 cases found in the decade, subsequent history was known in 10; 8 out of 10 died the month after the operation, the 9th died at the end of ten weeks and the 10th died seven months after a second operation, which followed the first. Other conditions mentioned and discussed are tumors and goiter. He thinks that advanced knowledge in the future should be in the direction of limiting unnecessary and harmful operations, greater accuracy in the diagnosis and prognosis and increased knowledge of pathology and pathologic anatomy.

**27. Lobar Pneumonia.**—Stockton holds pneumonia to be a toxemia. Not every part of the patient's system resists it; the weakest one is apt to be the heart, or the blood-making organs may fail to react and we have a lack of natural leucocytosis. There may be a secondary toxemia develop from a crippling of the liver and kidneys and the nervous system may be so injured that rest is impossible. The functional activity generally is handicapped. We know, however, a few measures that can be tried in almost every case; one is a prompt calomel purge; another is the treatment of the skin, though we differ in our methods. In the Buffalo General Hospital he invariably employs hot mustard foot-baths following sponging. The general circulation requires attention and these methods relieve high pressure. The depressing drugs are but rarely needed. He has seen great benefit follow the cold bath after the method of the Brandt treatment. Depression of the heart is still more to be feared and his method of meeting this is to strengthen it if possible by the use of strychnia, giving it early, beginning with 1/30 of a grain every two to four hours and increasing it up to even 1/10 gradually if the condition demands it. Baths, nourishment and medication should as much as possible be given at about the same time that they may not interfere too much with rest. The patient should not be disturbed too much even if he sleeps beyond the expected hour, but the nurse should be ready the minute he awakes to prevent depression, nervousness, etc., by prompt administration of nourishment, strychnia and other stimulants, if necessary. We must also bear in mind that pneumonia is a local process, and he thinks it a source of satisfaction when hepatization of one lobe appears early in the disease. Delay appears to increase the toxic action. He gives a supposititious case where there was probable consolidation of the other lung and speaks of the desirability of postponing this. He thinks this can be accomplished, taking

advantage of the constitutional symptoms already described. It is a good plan to give an additional dose of calomel, to press the hot foot-bath, support the tissues by increase in the strychnin and resort to local measures to decrease the pulmonary congestion. The best method is blood letting, 4 to 6 ounces of blood from the arm and then use dry cupping very thoroughly over the threatened area. The cup should be large and the suction strong so that a decided impression is made, and liberal inhalations of oxygen have also tided the patient over the eminent danger. In "wandering pneumonia" he thinks approaching consolidation may be aborted in this way. Lobar pneumonia is a disease that needs almost the constant presence of the attending physician in the severe cases, not in the mild ones which have a tendency to abort early. There is one particular condition in which he thinks counter-irritation is advantageous, and that is where there is delayed resolution. He has seen immediate improvement occur after failure of other methods by the use of a large fly-blister. He thinks that we are not yet ready to dispense absolutely with counter-irritation in pneumonia. Finally, experience teaches him that the great fatality of senile pneumonia is mostly from the unusual toxemia, because of the inadequate functional activity of the organs of elimination. If, with stimulating, we at the same time sweat the patient and assist hepatic and renal secretion by proper means, our results will be better.

**32. Infiltration Anesthesia.**—Matas' paper is a description of an apparatus used by him which is practically an adaptation of the Potain aspiratory apparatus, identical with the contrivance described and illustrated by him in the *Philadelphia Medical Journal* of Nov. 30, 1900.

33. See abstract in THE JOURNAL, xxxvii, p. 1339.

**34. Trophoneurosis.**—The case reported and illustrated by Pearse is one of a young woman who had a heavy head of brown hair, which fell out completely within three weeks and was replaced two or three months later with a growth of snow-white hair. Some ten or eleven months since this there has been some slight return of color. There is absolutely no history of heredity of premature grayness. He thinks that trophoneurosis best explains the development of the alopecia and bleaching of the hair, but he does not express a favorable opinion as to the complete restoration of the former condition. There has lately been a general attack of herpes.

**35. Tuberculosis.**—The experience of the Rutland Sanatorium of Massachusetts is summarized by Dunham, who gives a tabulated statement of over 200 cases treated, with the average length of stay of six months. The disease was arrested in 42 per cent., very much improved in over 22 per cent., much improved in 15.4 per cent., improved in a slightly greater proportion and unimproved in less than 4 per cent. The medical management seems to have been largely symptomatic, with no routine treatment. Strychnia in small doses, iodine preparations, hypophosphites, tonics, creasote, ichthyol, methylene blue, etc., were administered according to indications. The term "arrested" as used, means a condition of apparent health. Outdoor life as much as possible is recommended; and he gives a diagram of a bed which is arranged so that the head of it, including the sleeper's head, can be shoved out of the window during the night, and in case of storms coming up he can easily pull himself back. He does not specially over-value the increase in weight under treatment. He thinks that sometimes it is not in itself a real gain. The question of exercise is discussed and says it is to be regulated largely according to the temperature. When a rise of temperature is at all prominent, complete rest in bed is enjoined. Measurement of the chest capacity and physical examinations are employed. As regards hemoptysis he has changed his opinion as to its cause and thinks that increased blood pressure is by far the most important element. It is much less likely to occur according to his statistics in old cases with excavations than in recent incipient cases, and improved drainage may have something to do with this as well as lowered pressure. An absence of drainage might favor hyperemia, causing tension and relief by hemorrhages. Exertion is also a potent factor in its causation.

The routine treatment for hemorrhage in the sanatorium is absolute rest, and quiet, cold fresh air, semi-erect posture, trunk and head cool, heroin for coughing and in urgent cases morphin hypodermically and bandages at the base of the limbs. Common salt and small doses of aconite are used in almost all cases. Ergot is never employed. Suprarenal capsule and calcium chlorid have been used with good results. Securing of free movements of the bowel is an important matter. Preparations of gelatin with a light liquid diet are ordered.

**36. Nephritis in Malaria.**—Moore gives the conclusions of his paper in the following: 1. Nephritis is not likely to occur in a single tertian infection for a short interval, say of five days. 2. A double tertian infection will produce a nephritis in a large percentage of cases if it runs only for a short time. Our percentage is 80 per cent., but I think this is too large. 3. The more chronic the case becomes of any infection the more likely to produce nephritis. 4. Malaria of long duration, or often repeated attacks will produce chronic renal disease as shown by continuous presence of albumin and casts. 5. Estivo-autumnal malaria probably gives the greatest percentage of cases of nephritis, 68.7 per cent. 6. The age of the patient, height of temperature, or specific gravity of the urine showed no relation to the presence of albumin and casts in our cases.

**41. Primary Intestinal Tuberculosis in Children.**—From a study of the subject and a careful review of the literature, Bovaïrd comes to the following conclusions: "1. That English reports alone show any considerable number of cases of primary intestinal tuberculosis. 2. That primary intestinal tuberculosis is a very rare affection among children in or about New York, little more than 1 per cent. of the cases of tuberculosis having this origin. 3. That the proportion of tuberculous cases found at autopsy in New York is lower than that of European observers. 4. That the evidence connecting tuberculosis among children with the consumption of milk of tuberculous cows is very scant."

**43. Temperature Fluctuations in Tuberculosis.**—Several cases are reported by Adams to illustrate the fact that wide fluctuations of temperature in the terminal stage of tuberculosis in children are not necessarily of immediate serious importance. He says that the temperature may reach 108, and in a few hours drop to 95 without any effect upon the child either mentally or physically. He explains the absence of collapse and the not unusual phenomena of hyperpyrexia by the assumption that some irritant acts upon the heat centers differently from that present in purely septic conditions.

**44. Guaiacol in Infantile Tuberculosis.**—Rachford insists on the importance of early diagnosis and treatment of tuberculosis in children, but the special purpose for which his paper was written is to call attention to the great value of guaiacol in these cases. The prescription which he has used is:

|                   |     |       |
|-------------------|-----|-------|
| R. Guaiacol ..... | 3i  | 3/75  |
| Lanolin .....     | 3ii | 7/5   |
| Lard .....        | 3v  | 18/75 |

M. Sig.: One level teaspoonful to be rubbed into the chest at bedtime each day.

This he has employed in almost every case of tuberculosis of infancy and children for the past eight years and is convinced of its value. In cases where acute symptoms are in abeyance he prefers a substitute of carbonate of guaiacol internally for the inunction treatment. It is easy of administration, and when mixed with a little milk and sugar can be given in powder without causing complaint. It is especially valuable in intestinal and mesenteric tuberculosis. Other remedies are also mentioned, such as creosote by capsule or inhalation, iodid of iron, etc.

**45. The Little Finger in Mongolian Idiots.**—West calls attention to the symptom of curve of the little finger which has been noted in Mongolian idiots, though it is not universally observed. It was first noticed by Telford Smith some fifteen years ago. He has examined over 600 average children and found that in a large proportion of these some curvature is found, and in nearly 20 per cent. a very marked curvature. The symptom therefore is not a characteristic one.

**52. Subphrenic Abscess.**—The symptoms, pathology, diagnosis, frequency, modes of onset, prognosis, etc., of subphrenic abscess following appendicitis are described by Elsberg, who illustrates his article with reported cases and gives an analysis of others. He describes his operation for subphrenic abscess which is by resection of about two inches of the ninth and tenth ribs somewhere between the scapular and anterior axillary lines, according as the exploring needle has revealed the pus anteriorly or posteriorly. They can be resected through one incision made in the intercostal space between them and will expose the diaphragm with the liver moving below, and pleural reflection in the upper part of the wound. If the pleura appears to contain pus, aspiration should be performed, and if it is found the cavity should be opened and drained. If, however, this is needless, the upper part of the wound should be packed with gauze and the needle made to perforate the diaphragm below the resected pleura. If it perforates the abscess it should be allowed to remain in place and used as a director. A small incision of the diaphragm along the side of the needle, dilatation of the small opening with dressing forceps, and drainage according to general principles are all that is needed. If, however, the abscess is so high in the dome of the diaphragm that it can only be reached by the transpleural route, the pleural cavity can be opened through the upper part of the wound. In some cases the inflammation has obliterated the costophrenic sinus so that the pleural cavity need not be opened, and great care should be taken in this case to avoid tearing the adhesions. If the pleural cavity has to be opened it should be done as rapidly as possible, an assistant making upward pressure against the liver while the operator makes a small incision into the pleura. By this upward pressure it is often possible to so closely approximate the diaphragmatic to the costal pleura that little if any air can enter the pleural cavity when the opening is made. Usually, however, one must be satisfied with limiting the quantity of air by this procedure. Sometimes it is impossible to unite the two pleural layers by sutures. Then all that can be done is to wall off the cavity carefully with gauze. Elsberg does not agree with Beck that aseptic tamponade of the pleural sac should always be done. Incision of the diaphragm and evacuation of the pus by drainage of the abscess cavity are performed as already described.

**55. Peritoneal Tuberculosis.**—Fenger reviews the literature of tubercular peritonitis and from a summary of the whole agrees with Borchgrevink that laparotomy is not an efficient method of operation in these cases. He restates Borchgrevink's conclusions as follows: "That the laparotomy, in strong patients in whom fever is absent and their condition of good nutrition speaks for a spontaneous disappearance of the tuberculous process, is well tolerated. Laparotomy, however, in patients with fever, when the tuberculosis has a progressive character, must diminish what slight power of resistance such a patient has remaining. This power of resistance may thus yield, and death follow, or it may, by concurrence of fortunate circumstances, rebound, and the patient recover in spite of the operation. That form of peritoneal tuberculosis which exists without fever, or with only slight fever, runs in itself a favorable course. In such cases laparotomy is unnecessary. In progressive tuberculosis the operation is dangerous and should be abandoned."

**58. X-Ray Burns.**—Huntington reports a case of treatment of x-ray burn by excision and skin grafting, which he thinks is an efficient method of treatment of this condition. The excision should be performed through the external border so that all tissues supplied by the defective blood vessels are removed.

**64. Ablatio Placentae.**—This condition consists in the premature detachment of the normally situated placenta, and is extensively discussed by Holmes, who gives a long list of the literature. He finds it occurs about once in 200 pregnancies, and is of clinical importance in about 1 in 500. The difference between the occult and open type is largely dependent upon the external bleeding in the latter. Complete blood retention in the former generally produces an exaggeration of the uterine distention and accessory tumor and more evident shock.

Ablatio is practically an abortion in the latter months of pregnancy. The etiology is nearly identical, the mechanism in certain respects similar; there is often a paralleled threatened abortion. The patient may and often does tide over the difficulty in the mild cases and go on to term. The mild cases must be most carefully watched, quiet induced by morphia if necessary, icebags to the uterus, hydrastinin given instead of ergot, etc. In severe cases treatment will have to be modified by the condition of the os. If this is ready for delivery use forceps, craniotomy and version, using the operations in the order named. Version should never be selected except when unimpeded breech extraction is possible. In severe cases of labor, the labor should be induced as rapidly as possible by friction, electricity, quinin and sugar, general stimulation, etc., and preparation should be made to introduce a Barnes bag. Later the use of larger bags, manual dilatation, or Dührssen's incision when the effacement is complete and he suggests that the oblique cuts offer less danger than those suggested by the originator. If dilatation is present without effacement Dührssen's incisions have no consideration. In severe cases in labor hasten it as much as possible. Tampons should have no place in the treatment. The membranes should be preserved intact until delivery may be expedited. Cesarean section will be of value in selected cases, but never will be popular. If the placenta does not follow the child at once, remove it immediately. Be prepared for postpartum hemorrhage, which is a frequent sequence of the condition. Tampon the uterus early. The best remedy is extraction of the fetus. Apply this precept too early rather than too late.

**66. Recovery After Hysterectomy.**—The various facts brought out in Broun's study lead him to the conclusion that: "1. While the finished result of a supravaginal hysterectomy is most satisfactory, the operation is, however, marred by the possibility of a secondary infection, at times terminating fatally. When this infection does occur it can be reached only by some secondary operation. 2. The chance of this infection occurring is greatest when the subperitoneal space is drained through the canal of the cervical stump, or when the canal is left open. There is every reason to close the stump, as offering the best results. 3. Total abdominal hysterectomy, though not such a finished operation as the supravaginal, is, however, one in which there is less likelihood of any secondary complications, and, though objectionable on account of the suppurating cavity to be closed by contraction and granulation, yet offers to the patient a surer means of uninterrupted recovery. This conclusion, while at variance with Olshausen's large collections of cases, in which he gives a 5.6 per cent. death rate for supravaginal and a 9.6 per cent. rate for fatal hysterectomies, is, however, the only one to be drawn from this collection of consecutive cases brought together here."

**67. Post-Cervical Incision.**—Three cases are reported by Stinson of pelvic inflammation and from the study of these and other reported cases and a comparison of the methods, he draws the following conclusions: "1. That intraperitoneal pelvic inflammation is strictly a surgical disease. 2. That such inflammation should be operated upon as soon as the diagnosis is made, no matter what the state of the disease. 3. That in most cases the disease is best approached and cured through the posterior cervical cul-de-sac incision. 4. That all such inflammatory masses should be freely opened, the cavities thoroughly irrigated with hot antiseptic solutions, dried, and drained with loosely packed borated gauze strips. 5. That gauze drainage should be supplemented and aided by copious vaginal douches of 1 to 1000 hot watery solutions of potassium permanganate, given every three or four hours until discharge, fever, etc., are gotten under control. 6. That the cul-de-sac operation is extremely satisfactory in the treatment of intraperitoneal pelvic inflammation and most of its sequelae; the possibility of infecting the general peritoneum is very much reduced by operating through the cul-de-sac, as all fluids in the pelvis can be easily and thoroughly evacuated along lines of gravitation. 7. That the vaginal incision, when performed early in the disease, cures nearly 100 per cent. of all cases; and while the late vaginal incision is not always so certainly cured, it is

equally important. 8. That in all cases wherein diffuse peritonitis is present one is obliged to complete the operation at once with laparotomy, etc.; for this reason the patient, instruments, etc., should always be prepared beforehand, in readiness, if need be, for very extensive intraperitoneal operations. 9. That the vaginal operation for pus in the pelvic cavity is less difficult to perform than when done through an abdominal opening, and although the surgery is less complete, yet the dangers are less to the patient."

**74. Purpura Hemorrhagica.**—Schram reports a case and discusses the literature. In the blood there was found a number of small, rapidly rotating bodies which had been observed previously by Letzerich and considered by him as spores, but cultures taken from the blood 36 hours before death with all possible aseptic precautions gave pure cultures of staphylococcus aureus on all media. The bacilli found by Letzerich did not seem to have been present or at least could not be produced in the cultures.

**76. Rawed Peritoneal Surfaces.**—The treatment of raw peritoneal surfaces in the abdominal cavity after operation is taken up by Webster, who thinks it has been too much neglected in the past. It is a bad thing to leave such surfaces to produce adhesions. Small patches on the peritoneum, bladder, broad ligaments, etc., can often be sewed up at once with catgut. The areas of omentum which have been freed from adhesions should never be left open; if slight they should be covered with the neighboring omentum; if extensive they should be ligated near their base and then cut away. Adherent portions of appendices epiploicae should be removed after separation and the raw stumps buried. Raw surfaces on the intestine may be covered with continuous catgut suture, if small, but large ones can not be thus managed, and in some instances it is advisable to detach the flap of the parietal peritoneum if it is lax, or if not, he prefers to cut a thin flap from the omentum and stitch it on the raw surface of the bowel, closing the omental wound with catgut again. In very bad cases it may be advisable to resect the affected portion of the bowel, especially if much of the muscular layer is exposed. On the uterus a small surface may be sometimes covered by a running suture, but if large and numerous, drafts on the omentum may be made. He frequently cauterizes such raw surfaces so as to form a black char, which is less likely to become adherent than a raw, oozing surface. He always cuts or eures free tags of adhesions close to their base and buries the stump, if possible, under neighboring peritoneum. A thick char can not be produced on the bowel, which can only be lightly touched with the cautery. In removing diseased tubes or ovaries he has entirely abandoned the old-fashioned method of massing the tissues together in ligatures and leaving a raw projecting pedicle. It is more satisfactory to produce no tension in the pedicle and leave no raw surface. If the ovary alone is to be removed it is simply to be cut away at the hilum, the raw surface on the back of the broad ligament being constricted and covered by a double row of continuous catgut. If the tube is to be removed the same procedure is to be carried out, the uterine end of the tube being cut out of the uterine wall to the depth of a quarter of an inch, or burned out when there is any possibility that it is not sterile. When the ovaries and tubes are to be removed he passes a ligature around the upper part of the infundibulo-pelvic ligament to secure the ovarian vessels, and another around the upper part of the broad ligament close to the uterus below the tube to secure anastomosing branches of the uterine vessels. The ovary and the tube are then removed, the uterine end of the latter being cut out of the uterine wall as above described. The raw area of the broad ligament of the uterus is closed and covered with peritoneum by continuous catgut suture. In vaginal extirpation he always tries to draw the ligatured ends of the broad ligaments downward, stitching them into the lateral fornix so that the raw stump remains entirely within the vagina. Within the last two years he has used the following plan when double tubal or ovarian swellings have been adherent behind the uterus, and when removed a raw oozing surface is left. In marked cases in order to cover the raw surfaces he has removed the diseased

swellings and the entire uterus with the exception of its anterior peritoneal layer, leaving this continuous with the broad ligaments, bleeding points on the cut surface of the peritoneal layer and of the vagina being secured. A strip of gauze is passed into the vagina, its ending resting in the pelvis just above the opening in the fornix. The broad ligaments with intervening peritoneum thus forming a flap extending across the pelvis is turned backward and stitched around the wall, so as to form a new covering on the pelvic floor. The same procedure may be carried out after removing bilateral broad ligament tumors where a large raw area is left in the pelvis. After these operations there is always some oozing of blood into the vagina but not to any marked extent. The gauze can be removed on the second or third day according to the amount of discharge and a fresh piece inserted.

91. This article has appeared elsewhere. See THE JOURNAL, XXXVII, 522, p. 1728.

92. **Myositis Fibrosa.**—A case of this condition is recorded by Biggs, who reviews the condition, pointing out its varieties, the primary or idiopathic and the secondary due to trauma, ischemic disturbance, the site of the previously existing abscess or as a sequela of the non suppurating forms of myositis, such as rheumatism, syphilis, etc., those cases due to the presence of trichina in the musculature and those cases occurring in conjunction with scleroderma. The symptomatology is described. The site of predilection is in the leg, the thigh and lower leg alike; there is seldom any febrile reaction or constitutional disturbance of importance, but spontaneous pain occurs with tumor and some tenderness to pressure, possibly disturbance of the thermic or tactile senses. In the secondary form we have a wider distribution of disease. It is most commonly met with in torticollis with less spontaneous pain, less tenderness as the disease subsides into the chronic state and the muscles come to a certain extent to be substituted by fibroid tissue with loss of strength and electric reaction. The prognosis is usually favorable, the condition yielding to prolonged massage and electric treatment. The case reported is apparently one of the primary idiopathic form.

94. This article has appeared elsewhere. See THE JOURNAL, XXXVII, 522, p. 1728.

100. **Transmission of Tuberculosis.**—Brown does not believe in the transmission of tuberculosis from milk and the flesh of tuberculous animals. He classifies the infectious diseases of animals, pointing out that diseases of a long period of incubation and slow onset, slightly influenced by treatment, are seldom transmissible, and asks why tuberculosis should be an exception.

107. **Gunshot Wounds of Abdomen.**—A case is first reported and the condition generally discussed. Le Conte recapitulates the most important points as follows: "1. Remove the patient at once to the nearest place where a clean operation may be undertaken. 2. Assure yourself positively that penetration has taken place. 3. Having demonstrated this fact, always open the abdomen and search for injuries, and make this search systematic. 4. Never wait for symptoms to tell you that profuse hemorrhage or intestinal perforation has taken place, for by that time operation will usually be useless. Lastly, remember that cleanliness and thoroughness must never be sacrificed to speed. These two are absolute essentials to success, while speed is no longer an important factor since the introduction of normal salt solution."

108. **Sporadic Trichinosis.**—DaCosta and Dorsett report a case in detail, of which the particular features are that traumatism preceded the apparent onset of the muscular trouble; that pain in the muscle was slight; tenderness of the muscle and edema of the skin were absent; that no antecedent gastro-intestinal attack occurred; that, in spite of the widespread invasion, some diseased muscles (the deltoid) did not appear to be swollen and were not tender and painful, and other invaded muscles (the opposite lower extremities) were enlarged, but gave no evidences of pain, and finally, that eosinophilia was never noted. The relation of traumatism to the trichinosis is a point of interest and he suggests several ques-

tions, for instance, whether the seat of injury constituted the point of least resistance toward the larva trichina as injury often does towards micro-organisms. It is peculiar that the disease should begin in such an unusual situation as the calf of the leg where the injury had occurred. In the conclusion of the paper Dr. Coplin suggests the possibility of a recrudescence of lesions, basing it on the more or less local active lesion (trichina, edema, myositis, etc.), with quiescent trichinae in other muscles, the absence of marked eosinophilia, the history of the injury and the fact that injury induces inflammation of fully encapsulated, but quiescent, parasites of other but similar types, such as the echinococcus, and lastly, the evident pericapsular lymphoid accumulation, which he thinks establishes that the inflammatory phenomena which are present at the time are not necessarily related to the presence of living trichinae.

110. **Aortic Aneurysm.**—Freeman concludes that with the present inefficiency of medical treatment and the comparative efficiency of the use of silver wire and electricity, it is probably better to resort to the use of the latter at once. The prospect of cure is, of course, in the early stages when the sac is firm and the patient in good condition. Soft unalloyed silver, devoid of spring, is preferable to hard elastic wire. It is hardly necessary to previously coil it. It is still an open question as to which is preferable, a large or small amount of wire, but theoretic advantages are in favor of the former. A strong electric current is apparently preferable to a weak one. The cannula through which the wire is introduced should be inserted just within the sac and no further. There is little if any danger of bursting the aneurysm from increase of pressure due to coagulation in a portion of the sac only. Hall reports two cases in which Freeman employed this method.

117. **Lymphocytosis.**—After reporting a case, White concludes that lymphocytosis may result where there is an absence of enlarged lymph glands, from increased lymphoid tissue in the intestines and that the presence of these cells in the blood stream is probably due to mechanical causes (Ehrlich), and that lymphocytosis in the blood stream plays no part in the original inflammatory condition.

118. **Mastoid Suppuration.**—Phillips insists on early operation in mastoid diseases where a permanent remission of symptoms has not been brought about by free drainage through the drum membrane, by ice coils or poultices or by local blood-letting, and there should be no delay in operating under these conditions. The sooner it is done the better. Better hearing results will follow early operation as well as the chances of saving the patient's life. Pus pent up in mastoid cells is in a position to seriously menace vital structures. The method of operation adopted should meet one need, viz., the removal of all diseased tissue. He does not believe in the Wilde incision; local blood-letting can be obtained by much simpler methods. In cases of chronic suppuration the only hope of permanent relief is by external operation and we should certainly make an attempt to cure these cases.

124. **Blood Pressure.**—Carter's conclusions are that the average normal mean arterial pressure is for males 116 mm. Hg.; females, 113 mm. Hg. In acute nephritis the accompanying arterio-sclerosis, if present, is of slight or moderate degree. In acute nephritis the height of the blood-pressure varies, for the most part, directly with the amount of albumin in the urine. An acute parenchymatous nephritis complicating an acute infectious disease causes little or no increase in blood pressure. The average mean arterial pressure in chronic nephritis is about 62 mm. Hg. higher than that of acute nephritis. There were no cases of chronic nephritis seen without an accompanying arterio-sclerosis. In arterio-sclerosis it is only those cases in which it is extreme that the average mean arterial pressure is raised. The most satisfactory drug for lowering blood-pressure, whether increase is due to nephritis or marked arterio-sclerosis, is sodium nitrite, best given in 2 to 3 grains every two to four hours. It acts in about twenty-six minutes, causing a reduction of 10 to 15 mm. Hg. (in marked arterio-sclerosis sometimes much more), the effect last-

ing one hour and forty-four minutes on the average. When the blood pressure is high and is accompanied by symptoms of uremia the best method of rapid reduction is phlebotomy, 5 to 8 ounces, followed by saline infusion (1400 to 1500 c.c. of hot normal salt solution) and sodium nitrite in full doses. Clinically, also, there is almost invariably improvement. Blood-pressure in aortic regurgitation, whether complicated by nephritis or not, is slow. If a mitral regurgitation is also present pressure may be nearly normal. Blood-pressure in all forms of anemia is below normal. Possible relation is suggested between lowered pressure in chlorosis and the production of gastric ulcer.

**128. The Identification of the Colon Bacillus.**—Rosenberger concludes that, while not affording a specific reaction in the case of the bacillus coli communis, neutral red agar should be classed as a valuable differentiating medium. The typhoid bacillus, while it does cause a fading of the color of the medium, never gives rise to the fluorescence noticed in some cultures of the bacillus communis. Further, the test medium should not be depended upon as the only differentiating one in examination of water, as several very common bacteria found in water give the same reaction.

**129. Abscess of the Liver.**—The points of interest in the case reported by Scott are the clinical latency with no history of previous dysentery, sudden rupture into the right pleural sac with signs of acute hemorrhagic pleurisy and development and appearance and disappearance of pyopneumothorax. The pathologic points of interest are: 1. The character of the pleural exudate: A thin brownish-red fluid, with a heavier brownish flocculent sediment, containing fatty leukocytic cells, looking like liver cells; bile pigment, fatty crystals, but no ameba, and sterile on culture. 2. The characteristic large single abscess in the right lobe, and its thick wall and viscid pus. 3. The very old lesion in the colon. 4. The curative powers of nature, which were well marked in this case, as seen in the extensive thickening of the pleura, obliteration of the diaphragm, and the two attempts to get rid of the pus through the diaphragm and rupture through the bronchi.

**130. Aneurysm of the Heart.**—The case reported by Curtin is considered of interest by him, 1, on account of the size of the cyst opening from the left ventricle which was as large as a child's head; 2, on account of the patient having lived for years not only with greatly diminished breathing capacity and severe complicating cardiac condition; and 3, the fact that the removal of 235 c.c. of blood, to accomplish which must have caused a break in the continuity of the aneurysmal walls, failed to produce any symptoms whatever.

**138. The Chinese in San Francisco.**—The President of the San Francisco Board of Health, Dr. Williamson, reports the difficulties which they have with the Chinese population, their absolute rejection of sanitary methods, their gregarious habits which make ten of them occupy the space where one could properly do so, their opium smoking, evasion of regulations, dirt, morals, etc. He says if we want relief let us have the continuance of the Exclusion Act; if we want a repetition of the labor troubles, more opium dens, prostitution, dirt, leprosy, tuberculosis, bubonic plague, then let us have the brotherhood of man in all the fulness thereof, as regards the Chinese.

139.—See abstract in THE JOURNAL, xxxvii, p. 1628.

**Creosote in Pneumonia.**—In the abstract of Dr. Van Zandt's article in our issue of December 28, the dose used by him is given as  $7\frac{1}{2}$  to 10 grains or minims every three hours to an adult. It should read carbonate of creosote, as the action of creosote itself would be altogether too irritating. The carbonate of creosote can be given in much larger doses than creosote without causing gastric irritation.

British Medical Journal, December 21.

**Bacteriologic Examination of Potable Waters from the Public Health Point of View.** A. C. HOUSTON.—The points mentioned as specially worthy of note in this article are: "1. That from the public health point of view knowledge is

required, not so much as regards those microbes proper (peculiar, as it were) to pure water, but rather as regards those micro-organisms which are to be thought of as being of an adventitious, and possibly of a dangerous sort. 2. That as sewage is the most common and dangerous source of the pollution of potable water, further knowledge is required of the bacteria characteristic of sewage. 3. That bacteriologists have hitherto almost entirely neglected the question of the relative abundance of micro-organisms of different sort in pure and impure substances—for example, water as compared with sewage, virgin soils as compared with polluted and cultivated soils, etc. 4. That attention to this question of relative abundance has a most important bearing on the bacterioscopic analysis of potable waters from the public health point of view, because it shows that the biologic distinctions between pure and impure substances (for example, water and sewage) is so great as to be almost inconceivable, so great as to render the adoption of rigid and stringent bacteriologic standards unnecessary and inadvisable, and so great, also, as to allow the bacteriologist to detect in a water the presence of objectionable polluting material in quantity so small as to be far beyond the reach of chemical analysis. 5. That streptococci are absent from 10 c. cm. (or more); B. coli from 1, 10, it may be 100 c. cm. (or more); and B. enteritidis sporogenes from 100 to 500 c. cm. (or more) of pure waters; that is, these microbes are altogether absent or relatively so from pure waters. 6. That streptococci, B. coli and B. enteritidis sporogenes are commonly present in 1/1000 c. cm., 1/100,000 c. cm., and in 1/100 to 1/1000 c. cm., respectively, of crude sewage; that is, these microbes are present in crude sewage in great abundance. 7. That it is evident from these figures that there are tests available to the bacteriologist in the bacterioscopic examination of potable waters which far surpass in delicacy any known chemical tests. 8. That a stage may be reached in the pollution of water with sewage when the contaminating material is so small in relation to the bulk of water as to be inappreciable by chemical means, while yet yielding to bacteriologic tests unequivocal evidence of gross pollution with microbes of intestinal origin. This is a matter which has passed the stage of controversy. 9. That the presence of streptococci are to be thought of as indicating extremely recent, and B. coli less recent, but still not remote, pollution of animal sort, but that the presence of B. enteritidis sporogenes can not be considered to afford evidence of pollution bearing a necessary relation to the recent evacuation of animals. 10. That streptococci and B. coli are either altogether absent or present in sparse amount in virgin soils, and may be absent even from the polluted soils unless the contamination is of comparatively recent sort. In soils recently polluted with animal matters streptococci and B. coli are, of course, present in abundance. B. enteritidis sporogenes may be present even in seemingly virgin soils, but in sparse proportion compared with the large number found in cultivated and polluted soils. 11. That the presence of streptococci in any number in a water supply points not only to recent animal pollution, but also implies that the antecedent conditions—conditions intervening between the period of pollution of water and the time of collection of the sample—could hardly have been of so unfavorable a character as to destroy the vitality of seemingly more hardy microbes—for example, the typhoid bacillus. Quite the same can not be said for the B. coli test, since B. coli is a more hardy germ than B. typhosus. 12. That organic matter *per se* is, so far as we know, harmless; it is the bacteria apt to be associated with the organic matter that constitutes the element of danger. 13. That the amount of organic matter in a drop or even a few drops of sewage is so small as to be hardly appreciable on chemical analysis, and yet a like quantity of sewage can be shown by bacteriologic tests to harbor objectionable germs in great abundance. 14. That it is not necessary to demonstrate in a polluted water supply the presence of definitely pathogenic microbes to prove that there is danger in drinking such water. 15. That it is sufficient to show that microbes of intestinal origin are present in a water to condemn that water, because it is beyond controversy that

these micro organisms are apt at any time to be accompanied by other bacteria which are clearly shown to cause disease in human beings. 16. That the bacteriologist can show that between a pure water and a water contaminated even with minute traces of excremental matter there exists a biologic difference not only of degree but of kind. 17. That under like conditions the chemist may fail to appreciate the pollution altogether, and most certainly can form no conception of its dangerous character. 18. That the chemist's methods of endeavoring to ascertain the truth in the analysis of water are necessarily indirect ones, and that all standards of potability are based on an assumed relationship which may or may not exist between the amount of organic matter and the number and character of associated bacteria. 19. That valuable as the chemical analysis of a water undoubtedly is, it ought in the future to occupy a secondary position, and the bacteriologic examination take its place in judging the purity or otherwise of our water supplies. 20. That until these facts are recognized and acted upon, progress in the prevention of water-borne disease must needs remain unsatisfactory."

**On Rubella, Scarlatina and "Fourth Disease."** P. WATSON WILLIAMS.—The author is dubious in regard to the existence of the alleged "fourth disease." He reports cases which he thinks are difficult to explain. He shows a group of scarlatinal cases exhibiting all the features that Dr. Dukes relies on as indicative of "fourth disease" and thinks that some of the cases hitherto reported as "fourth disease" were rubella, scarlatina, etc. Rubella occurs in different types as also do influenza and scarlatina, and he remarks that when it can be shown that the type of "fourth disease" protects the patient from rubella and yet occurs in those who have previously had scarlatina, the evidence of its being a distinct exanthem will certainly be very convincing, but hitherto such evidence is lacking.

**Post Scarlatinal Diphtheria and Rhinorrhea and Otorrhea.** EGERTON H. WILLIAMS.—From a study of the hospital statistics of post-scarlatinal diphtherial nose and ear discharge, Williams offers the following as indicated from his study: 1. That it is advisable to cultivate all cases of rhinorrhea—aside from that of the acute stage—and otorrheas in scarlet fever cases, particularly in hospital practice. 2. That the bacilli at all resembling the diphtheria bacilli when found must be regarded as a modified variety of that organism, bearing in mind that their staining properties are often the only available means of diagnosis. 3. That systematic isolation of these rhinorrheas and otorrheas is not only justified but advisable. 4. That such isolation may be reasonably expected to reduce post-scarlatinal diphtheria incidence. 5. That it is an open question whether such mild cases require antitoxin treatment. Some cases, however, seem to indicate the use of the serum. It may do good and can do no harm. It is important also that these cases should be separated from healthy persons, even if they have not diphtherial disease. 6. That these discharges unassociated with sore throat, and therefore easily overlooked may be the cause of unaccountable outbreaks and the persistence of disease among school children.

**Pneumococcus Arthritis with Notes of Seven Cases.** NATHAN RAW.—Raw's conclusions are that from observation of a large number of cases of pneumonia he has found that the pneumococcus is capable of producing serious results in other parts of the body than the lungs. From his statistics he found that arthritis is a complication in 7 out of 817 cases of pneumonia or nearly 1 per cent., and his cases correspond almost exactly with those of Continental observers in that 6 were males and 1 female. In all 7 cases the pneumonia and the arthritis were both on the right side, which is probably only a coincidence though a striking one. He has also observed in some cases of pneumonia slight redness or pain of the shoulder joint of the affected side, but which subsided with the crisis. This may either precede the lung symptoms or follow the crisis or develop intercurrently. In Liverpool alcohol seems to decide in a great measure the severity of the attack, and he feels sure that one of his fatal cases would have recovered if he had not been a confirmed drunkard. The only treatment, in his

opinion, is early evacuation of pus, if it can be reached. It is just possible that many cases of synovitis and arthritis occurring either during or after an attack of pneumonia or altogether independent may be due to this organism. He suggests that the name Fraenkel's diplococcus would be better than pneumococcus as its designation.

The Lancet, December 21.

**Modern Methods of Vaccination and Their Scientific Basis.** S. MONCKTON COPEMAN.—The history of vaccination in England is reviewed and the methods of government production of vaccine described. The author calls attention particularly to the method of vaccination by first blowing the lymph from a capillary tube on an aseptic prepared portion of the skin, and then scarifying through the droplets. It is well not to be too hasty to apply dressing, and he remarks that when every care has been taken to protect the area during the progress of the vaccination and prevent premature detachment of the crust the amount of scar remaining may be astonishingly slight. This he thinks is one of the results of the modern methods of vaccination, and shows how unnecessary old extensive scars are, which are due undoubtedly to mixed infection. Copeman reports also an interesting fact in regard to the production of vaccinia in the calf. Calves are found immune to vaccine taken directly from natural cases of human smallpox. He followed the suggestion occurring to him that the original vaccine Jenner used must have been obtained from inoculated smallpox. He utilized monkeys, which are very susceptible, and succeeded in obtaining virus which was immediately effective on the calf. He also remarks that a corroboration of this has recently come to his knowledge that the use of human inoculated smallpox in Burmah was also capable of originating effective strains of inoculated vaccine lymph.

**Observations on the Etiology and Morbid Anatomy of Tuberculous Meningitis.** EDMUND CAUTLEY.—The records of 27 cases of tuberculous meningitis observed during life and afterwards examined in the dead-house are analyzed by the author. He concludes that heredity means exposure to infection of weakly or predisposed children; that injury is very rarely an existing or predisposing cause; that the respiratory tract is the great channel of infection; that the alimentary tract is very rarely primarily infected; that cow's milk is very rarely if ever a source of infection; that limitation of the tubercular process to the meninges is very rare; that the prognosis is very hopeless on account of the extent of the tuberculous disease elsewhere; and that operative treatment may be discarded as experimental rather than useful. As evidence of the slight danger of ingested tubercle bacilli he calls attention to the fact that children almost invariably swallow their sputum and yet in tuberculous children intestinal involvement is exceptional.

Bulletin de l'Academie de Medecine (Paris), December 3.

**The Respiratory Interchanges at High Altitudes.** A. ROUX.—The tests made on Dupasquier and others in the recent medical balloon ascensions at Paris are slightly contradictory in some points. Dupasquier found that his pulse became accelerated in an ascent lasting about three hours and attaining an altitude of 4250 meters, which is nearly 14,000 feet. The respiration increased in proportion to the altitude, but the breathing capacity and the respiratory quotient diminished inversely. The proportion of carbon dioxide decreased, while the proportion of oxygen increased during the entire ascent. The interchange of gases was promoted, especially the absorption of oxygen, which was triple the amount absorbed at the surface of the earth. The ventilation of the lungs increased with the altitude, but not in regular proportion. Tissot and Hallion also found that the oxygen absorbed increased from 3.52 and 3.6 c.c. to 6.16 and 6.46 in their tests, which are tabulated in the preceding issue of the *Bulletin*.

December 10.

**Importance of Potatoes in Diabetes and Diabetic Complications.** A. MOSSE.—The substitution of potatoes for bread in diabetes has proved a remarkably effective means of stimu-

lating the metabolism of sugar and thus attenuating the syndrome resulting from the diabetes. The general and local improvement has been so marked in Mossé's experience with 20 patients during the last five years that he thinks it must be ascribed to some special chemical combination in potatoes—probably the potassium salts. He found an average of 4.9 gm. of potassium to the kilogram of potato in his tests. He orders potatoes in an amount three times the amount of bread previously consumed. This supplies six times as much water, and three times as much mineral salts. It is in fact an "alkaline cure" like a course of Vichy waters. Under the influence of 500 to 3000 gm. of potato a day—generally about 1000 to 1500 gm.—the thirst rapidly and almost immediately diminished, also the glycosuria, while all the urologic symptoms were attenuated, coinciding with a general improvement. The neuralgic pains disappeared and rebellious sores and wounds in the diabetics rapidly healed. The potassium salts in the potato are in a vitalized form, and probably combine with the organic acids to form potassium carbonate. The improvement obtained on this potato diet was confirmed by a course at Vichy, in two instances. In the one case in which it failed, Vichy was also ineffectual. This patient was a woman of 47 with moderate arthritic diabetes, well tolerated, and existing for several years. In case of diabetic coma it might be possible to obtain good results from injections of an extract of potato chopped and squeezed in a bag.

Semaine Medicale (Paris), December 4.

**Bladder Disturbances in Syringomyelia.** J. ALBARRAN.—Only one of 6 patients with syringomyelia that happened to be inmates of the Bicêtre at about the same time recently, was free from bladder trouble. There was latent retention of urine in 3, one had cystitis with ulceration of the bladder walls, incomplete retention and secondary cord formation. Another presented total retention and a large ulceration in the bladder. Bladder troubles seem, therefore, to be frequent, contrary to the generally accepted opinion. They may be latent, merely an incomplete, aseptic retention, but this condition offers a very favorable soil for the development of infections. Trouble follows when the infection attains a certain intensity or when the retention is sufficiently pronounced to determine mechanical oppression. The lesions in the bladder differ anatomically from those of ordinary cystitis consecutive to retention. The ulceration is liable to lead to perforation and the process is evidently trophic, dependent upon a neuritic or medullary lesion. Trophic changes are frequent in syringomyelia, and it is not surprising that they should be encountered in the bladder. The ordinary lesions following aseptic or infected retention develop thus on a peculiar trophic soil. The contracting power of the bladder is liable to become impaired early. The ulceration may entail perforation and death, as in one of the cases described.

**Modifications in the Respiration and Blood in the Medical Balloon Ascents.**—Chauveau reported at the meeting of the Société de Biologie, November 30, that blood drawn from a dog at different times during the ascent to 3450 meters showed that the amount of carbon dioxide in the blood increased very much, but the increase in the amount of oxygen was but trifling, while the nitrogen was materially diminished. Jolly reported that tests on himself and Bonnier showed an increase in the red corpuscles of 12 per cent. The number increased from 4,760,000 on starting to 5,333,000 at 4450 meters and dropped to 4,800,000 at 2600 meters. The hemoglobin varied parallel with the number of corpuscles, attaining a proportion of 14 and 15.5 per cent. No modifications in the leucocytes were observed and no nucleated reds were discovered. Henry reported a similar increase in the reds in two dogs taken on the trip. The increase in the reds was much less marked in a third dog whose spleen had been removed a few weeks before. Bonnier noticed on the trip that his sense of hearing was diminished, but the transmission of sounds through the body was more rapid and more distinct than ever before.

Nouvelle Iconographie de la Salpêtrière (Paris), xiv, 4.

**Two Cases of Achondroplasia.** R. CESTAN.—The want of normal cartilage development results in abnormally short bones

from the early ossification of the cartilage. The muscles pile up on them until the limbs resemble the muscular development of the athlete. The fingers are spindle-shaped and spread apart at the tips like a trident. The subjects are frequently complete dwarfs. One of the cases described was a girl of 9. The photographs of 9 other cases that have been published are appended, with specimens of achondroplasia from museums and in art. Among them are the statuettes of the Egyptian gods Phthah and Bes, and the Roman emperor, Caracalla. Cestan attributes the condition to a toxic origin, and considers it a lesion extinct at birth. The achondroplasia occurs during the first months of fetal existence, before the thyroid gland has commenced its functions. Thyroid treatment, consequently, has no effect on it at any age.

**Two Cases of Achondroplasia.** E. APERT.—Both of the cases were male dwarfs. Apert emphasizes the hereditary character of achondroplasia, and calls attention to its occurrence in animals, especially in Ancona sheep, dachshund dogs, etc. He regards such types as a species apart; in man, at least a well characterized and hereditary type. It resembles in many respects the hereditary cleido-cranial dysostosis described by Marie. In fact the latter completes achondroplasia, as it affects the parts spared in the former. It is ossification from a membranous origin, while the other is from a cartilaginous origin.

Berliner Klin. Wochenschrift, November 25.

**Aid to Diagnosis and Prognosis of Inflammation of Optic Nerve.** J. HIRSCHBERG.—When one eye is covered, the pupil of the other eye becomes slightly dilated in normal conditions. This physiologic dilatation is about 1 mm. for a pupil diameter of 3 to 4 mm. In case of fresh inflammation of the optic nerve and consequent blindness, the pupil dilates to a remarkable extent when the sound eye is covered, and it does not contract when exposed to light. This pathologic dilatation is an infallible sign of the complete blindness of the eye. If it does not occur, the blindness may be assumed to be feigned or due to hysteria. In the first stage, the blindness occurs while the ophthalmoscope findings are negative. Then the findings become positive, and in the third stage, the blindness passes away, but it leaves a slight paleness. Hirschberg describes a case which passed through these three stages in one month. During the first two the pathologic dilatation was pronounced, but during the last stage the pupil contracted under the influence of light, thus showing that the blindness was subsiding and the prophecy of speedy recovery of sight was soon verified.

**Early Diagnosis of Arthritis Coxae.** J. A. BECKER.—The initial symptom of deforming arthritis of the hip joint is a difficulty in abduction. All the other movements of the thigh are normal, but abduction is painful. A hip splint should be applied at once with daily massage and movements. In a case described by Becker, this symptom was duly treated and cured, while the patient's brother was not treated until too late and a typical arthritis developed.

December 2.

**Adrenal Diabetes.** G. ZUELZER.—Blum's assertion that glycosuria appears in animals after injection of the extract of suprarenals, has been confirmed by Zuelzer's experimental research. As much as 4.4 per cent. of sugar was noted in one cat. The glycosuria, however, persists only 24 to 48 hours after the last injection. The proportion of sugar in the blood was also much increased. Further tests with alimentary glycosuria under these conditions showed a levulosuria of 0.9 and 0.5 per cent. in three animals after ingestion of 5 gm. of levulose. The glycosuria increased to 25 per cent. of the amount ingested after feeding with grape sugar. Lactosuria was also frequent after ingestion of milk sugar. The facts observed are chiefly interesting because the diabetes was induced by injection of what might be called a physiologic juice. [See editorial, December 28.]

Deutsche Med. Wochenschrift (Leipsic), November 21 and 28.

**Medicine and Life at Sea.** H. CURSCHMANN.—The subject

of tuberculosis among sailors was not mentioned at the recent London Antituberculosis Congress, Curschmann states, and yet the statistics of the Hamburg and Bremen hospitals show that 38 per cent. of all deaths among sailors is due to tuberculosis, and this does not include those who die at home or at sea. France reports 39 per cent. The proportion is practically the same in both the navy and the merchant marine. It is especially remarkable as the subjects are picked men in the prime of life. It illustrates the dangers of close contact between tuberculous and healthy men, and demonstrates that local relations and circumstances are capable of overcoming the most unfavorable general and personal conditions in unpredisposed individuals. The hygienic conditions on board ship for first and second class passengers are admirable, and a sea voyage may be a favorable factor in the cure of tuberculosis, but the crowded quarters occupied by the crew, the lack of facilities for bathing, washing clothes, and disinfecting, invite contagion. Persons in advanced stages of tuberculosis should not be admitted on ships on account of the danger for the crew, especially as steerage passengers. The health of the engineers and stokers suffers from the heat and confined air, with consequent heart and kidney affections and arteriosclerosis. Nocht ascribes to this cause 16 per cent. of all deaths among sea-faring men. He found a temperature of 37.7 C. in 35 stokers with the room at 24 C., and 23 had a temperature of 38 and higher (100.5 F.). Lauenstein observed a temperature of 38 to 38.6 C. in seven previously normal men of this class. Yellow fever is the greatest scourge of sea-faring men. It is the cause of 24 per cent. of all deaths in the hospitals and probably has a total mortality of 42 per cent.

**Parasitic Nature of Carcinoma.** H. RIBBERT.—The only rôle played by parasites in the evolution of a carcinoma, according to Ribbert, is in the primary irritation and inflammation in the connective tissue. This inflammation separates the epithelium from its normal organic relations and renders it independent of the body, except for its nourishment, thus allowing full play to its inherent, independent faculty of proliferation. It is possible that a specific microorganism may be the cause of the chronic primary inflammation in the connective tissue, but the subsequent proliferation is not parasitic.

**Statistics of Hereditary Tuberculosis.** F. F. FRIEDMANN.—In the 2984 cases of tuberculosis observed at the Berlin Charité between 1885 and 1901, hereditary antecedents were found in 983, that is, 33 per cent. of all cases; apparently negative in 751, that is, 25 per cent., and doubtful in 1250, that is, 41.8 per cent. Tuberculous brothers or sisters were mentioned in 35.6 per cent. of the 157 cases with both parents tuberculous; in 25 per cent. of the 503 cases with paternal inheritance; in 22.9 per cent. of the 323 cases with maternal inheritance; in 15.6 per cent. of the 1250 cases with dubious inheritance, and in 14 per cent. of the 751 cases with apparently negative tuberculous antecedents.

**Dangers of Simultaneous Administration of Mercury and Iodids.** F. LESSER.—Clinical and experimental tests with the salicylate, the thymol acetate of mercury, sublimate, and gray oil showed that they could be administered internally or applied locally while the organism was under the influence of potassium iodid, with impunity. No injurious results of any kind could be detected. But calomel applied locally or ingested, while the subject is under the influence of potassium iodid previously or simultaneously administered, forms with the iodine a caustic combination—the iodid of mercury—leading to abscess formation, ulceration, etc. No bacteria could be discovered in these ulcerations, which were exclusively of chemical origin. The iodine ingested in the form of potassium iodid is eliminated in the secretion on every mucous membrane, and when it comes in contact with calomel, the caustic compound that results is liable to form an ulceration, in the depths of which the yellow crystals of the mercury iodid are plainly visible. Rabbits treated with potassium iodid and then receiving a stomach injection of calomel, exhibited numerous ulcerations in the gastric mucosa, surrounded by a hyperemic zone showing the irritating action of the salt. The yellow crystals were found

in the ulcerations and also in the stomach contents. These caustic ulcers are liable to occur in any stomach after ingestion of calomel when the system is under the influence of potassium iodid. The physician should ascertain whether the subject has been taking potassium iodid before prescribing calomel, either internally or for local application on any mucous membrane. Calomel is the best test for iodine in the organism. It discloses the presence of potassium iodid even in a 1 per 100,000 dilution. The simplest application of the test is to add a little calomel to the saliva. If it contains traces of iodine, the calomel turns yellow. As potassium iodid passes into the milk, calomel should not be prescribed for nurslings when the mother is or has been taking potassium iodid. Calomel, mercuric iodid and the biniodid all share this caustic property. The pain and distress caused by the ulcerations in the stomach in persons taking calomel after potassium iodid, have never been correctly interpreted. The pains and vomiting have been attributed to the gastro-intestinal affection for which the calomel was originally prescribed. Cases have been described of inexplicable pains, scab formation and suffocation after the local application of calomel.

**Pregnancy After Nephrectomy.** STEINHEIL.—Five years after one kidney had been extirpated on account of a tubercular affection, the patient, a woman of 25, apparently in good health, but rather pale, consulted Steinheil in regard to a commencing pregnancy. She had been warned of the danger of conception in her case, and he hesitated whether to induce an abortion or to let the pregnancy take its course, deciding finally on the latter. The urine contained pus and was slightly blood stained. The pregnancy terminated normally and the patient recovered, with only the drawback that permanent catheterization was necessary for a short time. The child is healthy and the mother remained in good health for twenty-one months, when she succumbed to the extension of the tuberculous process. Whether she would have survived longer if the pregnancy had been interrupted is an open question. Steinheil states that he never felt such a burden of responsibility on his shoulders as when he had to decide in this case.

Die Heilkunde (Vienna), v. 4.

**Therapeutic Attempts to Promote Natural Processes in Tuberculosis.** A. HOFF.—The advantages of cinnamic acid and of alcohol are combined by Hoff, who treats pulmonary tuberculosis by the internal and external application of alcohol, supplemented by an alcoholic solution of arsenic and cinnamic acid. His formula is arsenic acid, 0.1; potassium carbonate, 0.2; cinnamic acid, 0.3—boiled with distilled water to make 5 c.c. Aqueous extract of opium is then added in the amount of 0.3; brandy, 2.5; and distilled water, 2.5. Six drops are to be taken in a spoonful of water after dinner and supper, gradually increasing the dose to twenty-two drops twice a day. THE JOURNAL has frequently referred to the benefits obtained from cinnamic acid as reported by Landerer and others in the treatment of tuberculosis. Kraemer's recent statistics show that objective success was attained in 72.8 per cent. after 14 injections; in 79.7 per cent. after 20 injections; in 80.7 per cent. after 24 injections, and in 86.1 per cent. after 40 injections. Patients treated for six months and more were completely cured in many cases, and the cures have persisted for more than three years. The local alcohol compresses were applied according to Buchner's directions. In cases of rapidly progressive emaciation and high fever, Hoff orders "Peru cognac" at first and follows later with his drop mixture, which is merely a more concentrated form of the "Peru cognac." He describes a number of typical cases to prove his assertion that this method of treating pulmonary consumption is the most rational, and all in all, the best. He has had several years' experience with it, and has applied it in numerous cases both in private and dispensary practice.

Muenchener Med. Wochenschrift, November 26 and December 3.

**Aid to Diagnosis of Appendicitis.** H. CURSCHMANN.—For the last two and one-half years, Curschmann has had the blood examined daily in every doubtful case of inflammatory

processes in the cecum or appendix, 60 in all. He found that it was possible by counting the leucocytes to differentiate every case of appendicitis with merely a so-called fibrinous exudate, from those entailing abscess-formation, even when all other signs, such as fluctuation, shape, consistency, temperature and exploratory puncture were the same in each. The cases without an abscess were distinguished by the fact that they ran their course without any increase in the number of the white corpuscles, or with merely a slight increase at first, returning permanently to normal, or with an isolated increase in a few days. Marked increase in the number of whites occurs in the absence of an abscess, only at the commencement of the inflammatory process, and then only transiently. The number never rises above 20,000 or 22,000 in this case. If the number of leucocytes is very high in the first days or in the further course of the inflammation and remains high, if there is no other process to which the leucocytosis can be attributed, such as pneumonia, etc., the formation of an abscess can be positively assumed and surgical intervention be unconditionally determined on. Leucocytes to the number of 25,000 and more, even if observed only once, are a very suspicious sign. If noted permanently as the process continues, the diagnosis of suppuration is certain, and further hesitation is unnecessary. When the abscess has been evacuated, the leucocytes drop rapidly to the normal proportion. If the number does not decrease or if it increases again, retention of pus or an abscess elsewhere can be confidently assumed. If the abscess perforates into the intestine or bladder and is thus evacuated, the leucocytes diminish as after a surgical evacuation. The number falls rapidly if the pus finds free outlet, more slowly if it meets with hindrance. The behavior of the leucocytes is a much more reliable index of the internal process than the temperature. Curschmann tabulates the findings in a number of typical cases, showing the constant behavior of the leucocytes while the temperature and other physical signs were frequently contradictory.

**Ovarian Treatment After Castration.** A. FLOCKEMANN.—Ovarian medication has proved perfectly harmless in Flockemann's experience, and has been successful in warding off unpleasant symptoms after bilateral castration in a number of patients. It is not invariably effective, but the proportion of successes is so large that it ought always to be given a trial in such cases.

Sammlung Klin. Vortraege, No. 318.

**Chronic Dyspeptic Diarrhea and Its Treatment.** R. SCHUETZ.—In 16 cases of chronic diarrhea persisting for years, Schuetz obtained a rapid cure in less than a week, by washing out the stomach and intestines and restricting the diet to articles made of fine flour, with six eggs a day, preparations of albumin, beef tea, and, in the milder cases, white meat. Red meat, milk and vegetables were barred. He believes that these cases of chronic, rebellious diarrhea are primarily due to gastric disturbances. The impaired stomach digestion is compensated at first by the small intestine. The intestinal digestion gradually becomes impaired, with resulting diarrhea, and finally, intestinal catarrh. Two-thirds of the patients had experienced flatulency and colic at times, with vague symptoms in the abdomen, but no distinct history of stomach trouble. A chronic gastric affection was evident in 2 patients and neurasthenia in a few others. One young girl developed later tetany and scorbutus. Nine were dispensary patients. The feces had an acid odor and were full of minute bubbles. The food frequently passed undigested. In the 14 cases in which the stomach was systematically washed out, gastric achylia was found but once. The total acidity averaged high, as much as 132 to 178. Most of the cases exhibited merely a diminished secretion of hydrochloric acid, with or without atony. The motor function was excessive in one case. Drugs to check the diarrhea are absolutely contra-indicated. The patients should remain in bed during treatment or lie down for five or six hours a day. An important adjuvant is hot Wiesbaden Kochbrunnen water before meals, and after meals a little dilute hydrochloric acid or natural gastric juice from dogs.

Wiener Klin. Wochenschrift, November 21.

**Diagnostic Significance of Fluctuation in Pleuritic Effusions.** R. VON STENITZER.—Fluctuation occurs in pleuritic effusions much more frequently than is usually credited. The waves are shorter than in case of ascites. By bending the trunk and raising the arm, the ribs can be spread apart. In case of an effusion on the right side the assistant stands at the left of the bed and places his hand flat with slight pressure on the back of the thorax, with the middle finger in the interspace selected for the percussion, preferably between the spine and the line of the scapula, and presses firmly with the middle finger, while the physician taps as for ordinary percussion, preferably in the seventh and eighth interspaces and region of the posterior axillary line. The discovery of fluctuation is valuable for the differentiation, especially in case of a moderate effusion. In one case with signs of a serous pleuritis in a tuberculous patient and fluctuation in the seventh to ninth interspaces, friction sounds became audible later, both during inspiration and expiration, and also in the fifth interspace. The presence of fluctuation differentiated the friction sounds as not due to the rubbing together of the sheets of the pleura, nor to deposits on the costal pleura, but to floating fibers of fibrin in the serous effusion, a kind of villous pleuritis. The lack of the pectoral fremitus and of change in tone with position renders the diagnosis of a pleural effusion particularly difficult in children. When the fingers are pressed into one interspace and the hypochondrium is compressed from below, the discovery of fluctuation aids materially in the differentiation.

**Meniere's Symptom Complex Cured by Electricity.** J. DONATH.—In case of Meniere's symptom-complex, before administering quinin, Donath advises the application of galvanic electricity with which he cured in one sitting a severe and rebellious case. Others have also had similarly favorable results.

November 28.

**Mesenteric Cysts.** V. BLUM.—In the case of cyst formation in the mesentery, described in this communication, recurring volvulus of the small intestine was noted, and Blum calls attention to this feature of the case as valuable for the diagnosis of these conditions. The patient was a girl, 6 years old. Five or six times in the course of a year she had suffered from violent pains accompanying constipation, but in the intervals presented no symptoms. The indications of volvulus disappeared four times after copious irrigation of the intestines, but at last presented the clinical picture of chronic invagination of the small intestine. A cyst the size of a fist was found in the mesentery, twisted several times on its axis, and the entire ileum was in a tangle around it. The child died a few hours after the operation and tubercular lesions were found throughout the mesentery and in one lung. Recurring attacks of intestinal occlusion in case of a soft, fluctuating, movable tumor near the umbilicus should suggest the possibility of a mesenteric cyst. The origin is probably tubercular or typhoid degeneration of some intestinal gland.

**Simple Fastening for Permanent Catheter.** L. MOSZKOWICZ.—A rubber tube about 12 cm. long is slit into four strips to within 3 cm. of the end. The tube should be just large enough to admit the catheter with friction. The ends of the four strips are fastened over another rubber tube. The catheter is passed through the unslit portion of the tube, doubled back inside the slit ends fastened to the second tube which serves for a strap. It is fastened around the glans or waist. This muzzle arrangement holds the catheter permanently in place and with slight modifications is also applicable to females.

Grece Medicale (Syra, Greece), September.

**Treatment of Pott's Disease by Gradual Reduction Without Chloroform.** N. ALIVIZATOS.—This method of treatment is adapted only for humps without ankylosis. The child reclines on supports at the knees and shoulders. A simple apparatus on a standard beside him accomplishes the

reduction by a gradual, slow, gentle, elastic pressure on the hump, while ropes from the same controlling wheel pass over a pulley at each end of the table, on the plane in which the child is lying, and exert extension and counterextension, at the same time, all from the same simple apparatus. The plaster cast is applied while the child is still in extension, without altering his position. There is no pain, and chloroform or any anesthesia is unnecessary. The hump should be radiographed as the first step, to determine the exact character of the lesion and to exclude those with ankylosis.

October.

**A Voice from Damascus on the Subject of Tuberculosis.** J. MARENGOS. The Bedouin encampments with their pure air, sunshine, simple manner of living and enviable health, are true sanatoriums, Marengos exclaims. Phthisis is unknown. He asserts that man has become tuberculizable since he neglected the development of his body, which the ancients regarded as an actual religion. According to the law of compensation, the benefits of civilization entail phthisis, the tent life of the Bedouins brings health. Tuberculosis was almost unknown in Damascus twenty years ago, but is growing more frequent every day. Malaria is declining. The 15,000 Jews in Damascus seem to be exempt from tuberculosis. Marengos recently discovered a young consumptive in a remote village far from all apparent sources of contagion, no other case known in the community.

**Treatment of Hydrocele.** P. DIVARIS. The fluid of the hydrocele will be absorbed if the absorbing power of the endothelium is reactivated. Divaris accepts this as the principle of his treatment, which consists in the evacuation of half of the fluid after an injection of cocaine. He then injects four grams of 90 per cent. alcohol. This stimulates the endothelium and causes the absorption of the fluid, thus curing without pain.

*Zeitschrift f. Diät. u. Phys. Therapie* (Leipzig), v. 4 to 6.

**Solid Food for Typhoid Patients.** A. DVORETZKY. THE JOURNAL has referred to the success obtained by the Russians in feeding solid food to typhoid fever patients. They claim that it is a mistake to assume that the digestive powers are diminished during a fever. Also, that the fear of perforation from solid food is unfounded, as by the time it reaches the portion of the intestines affected by the typhoid process it is no longer in a solid form. The danger of adding to the fever by a mixed diet is exaggerated, they state. If the temperature does rise a trifle, this drawback is far outbalanced by the benefits to the general health. The debility and symptoms during convalescence attributed to the typhoid toxins, are in reality merely the results of starvation from the usual fluid diet. None of the physicians who report their experience with non-fluid foods has lost a patient. All were comparatively strong and lively when the fever left them and could be dismissed much sooner than the control patients. Ladyshensky reports five cases fed throughout with eggs, poultry and chops, and in the later stages with fish, potatoes, etc. Tiemen reports 32 typhoid patients kept on a mixed diet. No complications were observed in any case. The abdomen was always soft and free from meteorism.

**Blood Pressure in Phthisics.** M. JOHN. About 120 patients with pulmonary tuberculosis were examined and the blood pressure and specific gravity of the blood were found normal in the early stages of the affection. As the tubercular process gained the upper hand, both decreased, before auscultation or percussion indicated the change. Both blood pressure and density are slightly above normal in case of emphysema.

*Zeitschrift f. Geb. u. Gyn.* (Stuttgart), xlvii, 1.

**Influence of Pregnancy on Cancer of the Uterus.** K. HENSE. Pregnancy or the menopause has undoubtedly an unfavorable influence on the development of malignant disease, but it is less deadly than some imagine. Hense has found 10 cases of survival for more than five years in 82 patients operated on for uterine cancer more than five years ago, during or

immediately after a pregnancy. Vaginal hysterectomy was done twenty-five times, with 9 permanent cures. French surgeons consider a pregnant woman with cancer as irremediably lost, and sacrifice the mother in favor of the child. In Germany, the surgeon operates at once, and without regard to the child. Hense has collected 122 cases of this kind. The cervix was the site of the lesion in all. Fraenkel found that 30 per cent. survived for more than five years without recurrence in 230 cases of cancer of the cervix not associated with pregnancy.

*Zeitschrift f. Heilkunde*, xxii, 8 and 9.

**Therapeutic Value of Venesection in Uremia.** K. WALKO. A dozen typical examples are reported to demonstrate the remarkable benefits to be derived from venesection and transfusion of saline solution in certain cases of uremia. The uremic symptoms subsided while quantities of blood-stained urine, rich in sediment, were voided, accompanied in some cases by profuse sweating and diminished albuminuria. These favorable results were obtained exclusively in cases of uremia with acute nephritis, or in acute exacerbations of mild, subacute nephritis. Venesection was nearly or completely ineffectual in cases of uremia with severe chronic nephritis or contracted kidney, amyloid degeneration or large white kidney. Tests of the blood before and after the uremic attacks failed to disclose any difference in the molecular concentration. The benefit of the venesection is probably due to its arresting the vascular constriction resulting from the uremic irritation of the vasomotor centers. Venesection is, therefore, indicated in all cases of acute nephritis in which diminished secretion of urine is accompanied by edema and high vascular tension. It may prevent its transition into a chronic form. Repeated hot baths are not indicated in the treatment of nephritis with uremia except when copious diuresis follows. Otherwise the loss of water from the tissues, combined with the retention of waste products, may entail severe uremic symptoms and even death, as in a case at von Jakseh's clinic whence this communication proceeds. Infusion of salt solution is a valuable adjuvant to venesection sometimes, when the edema is not too extensive.

**Glycosuria and Acetonuria in Case of Phosphorus Intoxication.** K. WALKO. Alimentary glycosuria was observed in 65.85 per cent. of 141 cases of acute phosphorus intoxication. The mortality was 30.4 per cent. In 6 cases there was spontaneous glycosuria. The liver suffers most in phosphorus poisoning, and the facts observed in these cases confirm the close connection between fatty degeneration of the liver and glycosuria. The alimentary glycosuria paralleled the severity of the intoxication, but afforded no data for the prognosis. Acetonuria was frequently observed in the first few days of the intoxication, but no connection could be discovered between it and the severity of the case or the alimentary glycosuria.

**Inferior Peritoneal Adhesions.** J. ALTENEDEK. Gersuny has now an experience of forty-two operations undertaken to relieve disturbances due to the formation of adhesions in the abdomen. Thirty-five cases were correctly diagnosed from the character of the pains, due to the special function or movements of the organs involved. Pain before and during micturition indicates adhesions involving the bladder. Gersuny's typical flexure adhesions cause pain just before defecation, and adhesions between the internal female genitalia are liable to induce displacements, with all their consequences, which include a liability to ectopic pregnancy as well as painful menstruation. Certain adhesions between the intestines and mesosigma entail constipation and a tendency to volvulus which can be cured by high rectal injections. Gersuny believes that chronic catarrhal inflammation of the appendix may result from the irritation caused by adhesions. The particulars of all his cases are tabulated; 12 were cured and 18 improved out of 33 followed to date. Failure to find all the adhesions or the formation of new adhesions was probably the cause of the non-success in the others.

*Zeitschrift f. Klin. Med.* (Berlin), xlv, 1 and 2.

**Varieties of Tumors in the Kidneys.** D. VON HANSE-

**MANN.**—There is scarcely any other organ in the body in which tumors occur so frequently and in so many varieties as in the kidney. Hanseemann supports this statement by reviewing the kinds of tumors that have been recorded, and divides them into four groups: 1. Tumors developing in the parenchyma, such as cystoma, adenoma or carcinoma. 2. Tumors in the stroma, fibroma or sarcoma, or they may develop from the connective tissue or from the vessels, forming hemangioma, lymphangioma, endothelial adenoma. 3. Tumors from embryonal aberration of cells. They may be of a single kind of tissue, such as hypernephroma, lipoma or chondroma, or they may be a mixture, as in teratoma, with or without malignant transformation. 4. Pseudo-tumors, such as cyst, echinococcus, hydronephrosis, etc.

**Influence of Cancer on Stomach Secretions.** O. REISSNER. —After extensive study of the chemistry of the stomach in cases of cancer, Reissner is convinced that the neoplasm has no influence until it becomes ulcerated. At this stage the poisonous products of the cancer become mixed with the stomach contents and the results are extremely injurious for both the stomach and the intestines. The absence of free hydrochloric acid in such conditions is due in part to its combination and partially to the inhibition of the secretion by the poisons in the stomach contents. This assumption explains the rapid atrophy of the mucosa and the absence of uncombined acid in case of cancer of the stomach, irrespective of its site and even when it is located in an adjacent organ. The secretion is not entirely checked, but the acid is neutralized. It also explains why the free hydrochloric acid shows less variation in case of a cancer developing on the foundation of an ulcer. Cicatricial tissue has less tendency to ulceration, and the cancer develops inward rather than outward. It also explains the rapid, often sudden, disappearance of the free hydrochloric acid, and its reappearance after the ablation of the tumor, in case the atrophy has not progressed too far. The practical results of the research reported are the warning to shut off the cancer from the rest of the stomach, in case it can not be entirely removed, in order to prevent the mixing of its products with the stomach contents.

**Pathologic Anatomy of the Stomach in Case of Ulcus or Carcinoma.** W. A. BOECKELMANN. —Scraps of the mucous lining of the stomach, obtained during a gastro-enterostomy, from 44 patients, showed nearly normal conditions in the cases of ulcer or cicatrices, even when the lesion had lasted for eleven to seventeen years. He found in 31 out of 53 cases that an increased production of hydrochloric acid coincided with an accumulation of cells covering the lesion, or with carcinoma developing on the foundation of an ulcer. In his experience, this latter variety occurred once to 3.9 primary cancers. The duration of the latter averaged five weeks to two years in his 26 cases, while the patients with post-ulcer cancers survived several years; ten and fifteen years in 2 cases. These 2 patients had 2.1 or 2 per 1000 acid while the highest proportion in the primary cases was 0.8 per cent. He emphasizes the good condition of the stomach lining in all the post-ulcer cases, and the excessive atrophy with an ulcerating cancer, either in the stomach or duodenum. He attempts to explain these phenomena by assuming that the post-ulcer cancer is rather a local process while the primary is more a general, constitutional affection. This assumption may be verified or overthrown, perhaps, by study of recoveries after extirpation of both kinds of malignant tumors.

Janus (Amsterdam), November.

**Discovery of Collodion.** G. W. A. KAHLEBAUM. —The encyclopedias mention Maynard as the discoverer of collodion, but Kahlbaum claims the priority for the German scientist Schoenbein. He published in December, 1846, the first description of the substance with its characteristic properties and its advantages for the treatment of wounds. C. T. Jackson in America, "the father of anesthesia," published January 6, 1847, that he had found a means to dissolve cellulose nitrate, and with his friends, Bigelow and Maynard, suggested its ap-

plication to the treatment of wounds. It was known in America as Maynard's adhesive solution for many years. Schoenbein called it xyloidin. The term collodion was first applied to it by A. A. Gould, secretary of the Boston Society of Natural History. Letters which Kahlbaum has found, dated at Geneva, Switzerland, February, 1847, mention that Schoenbein's new method of treating wounds was the sensation of the day, and in March, Jung published the reports of a number of cases treated with it. Communication between Europe and America in those days excludes the possibility that the scientists in either country could have heard of the discoveries across the water in such a short time.

Cronica Med. Mexicana (Mexico), December 1.

**Efficacy of Calcium Monosulphid in Diphtheria.** E. L. ABOGADO. —Experiences in Mexico are confirming the efficacy of the treatment of diphtheria with calcium monosulphid recommended by R. Tissot of Switzerland. It cures mild cases without further medication, and in severe cases proves a most valuable adjuvant to antitoxin treatment. He established its efficacy in 110 cases of associated diphtheria, in 21 of mild, pure diphtheria and in 13 severe, pure cases. None of the two last groups died. The monosulphid was the only therapeutic agent employed in any of the cases. Its efficacy is probably due to its action on the associated microbes as well as on the diphtheria germs, while antitoxin is powerless against the former. He usually administers 1 cg. every hour up to 1 year of age; 1 cg. every half-hour between 1 and 3; one every fifteen minutes between 3 and 5 or 30 during the day. Between 5 and 15, one or two every fifteen minutes or 49 during the day. Adults should take 60 during the twenty-four hours, suspending the medication whenever the breath exhales the characteristic odor very intensely. He administers 5 or 6 cg. a day as a preventive measure to children exposed to contagion. He considers it a very valuable internal antiseptic and has never known of any untoward effects from its use in this way during six years of experience.

Klinitchesky Journal (Moscow), October.

**Tubercular Peritonitis.** P. E. ELESTRATOV. —The statistics of a number of writers on this subject show that 31.6 per cent. of 136 cases recovered with medical treatment alone, while 78.3 per cent. of 240 cases recovered after surgical intervention. On the ground of his personal observation and the reports published by others, Elestratov asserts that the variety of tubercular peritonitis which runs an almost stationary or chronic course, with moderate temperature and not much ascites, without much interference with nourishment, is capable of retrogressing to permanent recovery provided no other organs are affected by the tuberculosis. On the other hand, when the existence of tubercular foci can be established, serving as the starting-point for infection of the mesenteric glands, intestines or uterine appendages, surgical intervention is urgently indicated.

Vratch (St. Petersburg), xxii, 1901, 34.

**Combined Ethyl Bromid and Chloroform Anesthesia.** E. F. ZEMATZKY. —A few drops of ethyl bromid on the mask put the patient to sleep so rapidly that he has no time to realize the process. Zematzky then substitutes chloroform for the bromid and states that this combination has all the advantages and none of the disadvantages of other methods. In less than a minute, usually forty-five to fifty-five seconds, the minimum twenty seconds and the maximum two minutes, the patient has passed successively through the phases of analgesia and anesthesia to loss of consciousness, with entire absence of excitement. No accidents of any kind were observed in Zematzky's experience with more than 2000 subjects thus anesthetized or in 1000 others where he was a spectator.

**Medical Use of Hypnotism.** P. ROSENBAACH. —Many nervous and mental affections against which the physician is otherwise powerless, can be effectively treated by hypnotism, which does not receive from physicians the consideration that it deserves. Rosenbach urges the profession to resort to it more

frequently in cases of cephalalgia, local spasms, morbid fixed ideas, phobias, insomnia, alcoholism, psychic impotence, enuresis, and other conditions resulting from neurasthenia, hysteria, etc. He appeals for relief from the regulations in Russia according to which no physician can hypnotize a patient except in the presence of other physicians and after due notification of the local medical authorities, stating not only the patient's name and the purpose for which the hypnotism is to be applied, but also the names of the witnesses.

## Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

**TEXT-BOOK OF HISTOLOGY.** Including the Microscopic Technique. By Dr. Philipp Stöhr, Professor of Anatomy at the University of Würzburg. Fourth American, based upon the Ninth German Edition. Translated by Dr. Emma L. Billstein, formerly Director of the Laboratories of Histology and Embryology, Woman's Medical College of Pennsylvania. Edited, with additions, by Dr. Alfred Schaper, Professor of Anatomy, University of Breslau. Cloth. Octavo, 500 pages. Price, \$3.00 net. Philadelphia: P. Blakiston's Son & Co. 1901.

**THE PRACTICAL SERIES OF YEAR BOOKS.** Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Issued Monthly. Under the General Editorial Charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Post Graduate Medical School. Volume II. General Surgery. Edited by John B. Murphy, M.D., Professor of Surgery, Northwestern University Medical School. November, 1901. Cloth. Pp. 515. Price, \$2.00. Chicago: The Year-Book Publishers. 1901.

**NEUROLOGICAL TECHNIQUE.** Some Special Histological Methods Employed for the Study of the Nervous System, Together with a Laboratory Outline for the Dissection of the Central Nervous System and the Neurological Nomenclature (BNA) Arranged in a Classified List. By Irving Hardesty, Ph.D., Instructor in Anatomy, University of California. Cloth. Pp. 183. Price, \$1.75 net. Chicago: The University of Chicago Press. 1902.

**THE MENTAL FUNCTIONS OF THE BRAIN.** An Investigation into Their Localization and Their Manifestation in Health and Disease. By Bernard Hollander, M.D. (Frelburg I.R.), M.R.C.S., L.R.C.P. (London). Illustrated with the Clinical Records of 800 Cases of Localized Brain Derangements and with Several Plates. Cloth. Pp. 507. Price, \$3.50. New York and London: G. P. Putnam's Son. 1901.

**AN EXPERIMENTAL AND CLINICAL RESEARCH INTO CERTAIN PROBLEMS RELATING TO SURGICAL OPERATIONS.** An Essay Awarded the Alvarenga Prize for 1901, by the College of Physicians of Philadelphia. By George W. Crile, A.M., M.D., Ph.D., Professor of Clinical Surgery, Medical Department, Western Reserve University. Cloth. Pp. 200. Price, \$2.50. Philadelphia: J. B. Lippincott Co. 1901.

**CLINICAL HEMATOLOGY.** A Practical Guide to the Examination of the Blood with Reference to Diagnosis. By John C. DaCosta, Jr., M.D., Assistant Demonstrator of Clinical Medicine, Jefferson Medical College. Containing 8 full-page Colored Plates, 3 Charts, and 48 Other Illustrations. Cloth. Octavo, 450 pages. Price, \$5.00 net. Philadelphia: P. Blakiston's Son & Co. 1901.

**THIRTY-SECOND ANNUAL REPORT OF THE MANAGERS AND SUPERINTENDENT OF THE NEW YORK STATE SCHOOL FOR THE BLIND.** Batavia, N. Y. For the Year 1899-1900. Paper. Pp. 45. Albany: James B. Lyon. 1901.

**TRANSACTIONS OF THE LOUISIANA STATE MEDICAL SOCIETY,** at Its 22d Annual Session, held at New Orleans, La., April 18, 19, 20, 1901. Cloth. Pp. 467.

## The Public Service.

### Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Dec. 19 to 25, 1901, inclusive:

Charles Anderson, captain, asst.-surgeon, Vols., honorably discharged from the service of the United States, to take effect Feb. 10, 1902.

David Baker, lieutenant, asst.-surgeon, U. S. A., relieved from duty in the Department of California and assigned to Fort McPherson, Ga.

Peter C. Field, lieutenant, asst.-surgeon, U. S. A., former orders directing him to proceed from Fort Slocum, N. Y., to Fort Robinson, Neb., revoked.

William C. Gorgas, major and surgeon, U. S. A., detailed by the Secretary of War to represent the Medical Department of the Army at the meeting of the Pan-American Sanitary Congress, to be held in the city of Havana, Cuba, Feb. 15, 1902.

George C. Grabenstatter, contract surgeon, from Buffalo, N. Y., to San Francisco, Cal., en route for duty in the Division of the Philippines.

Vernon J. Hooper, captain, asst.-surgeon, Vols., having tendered his resignation, is honorably discharged from the service of the United States, to take effect Dec. 31, 1901.

Henry M. Hull, contract surgeon, leave of absence for ten days granted.

Jefferson R. Kean, major and surgeon, U. S. A., detailed to represent the Medical Department of the Army at the Pan-American Sanitary Congress, to be held in the city of Havana, Cuba, Feb. 15, 1902.

Ellas H. Porter, contract surgeon, leave of absence for two months granted.

Albert H. Rimonten, contract surgeon, former orders directing him to proceed from Fort Robinson, Neb., to Birmingham, Ala., for annulment of contract, revoked.

Hair D. Taylor, major and surgeon, U. S. A., leave of absence for one month granted.

James W. Van Dusen, lieutenant and asst.-surgeon, U. S. A., now at San Francisco, Cal., to proceed to Columbus Barracks, Ohio, for post duty, December 19; leave of absence for one month granted.

Hugo A. Wall, contract surgeon, now at San Francisco, Cal., is relieved from duty in the Division of the Philippines, and assigned to post duty at Fort Strong, Mass.

### APPOINTMENTS, PROMOTIONS, CASUALTIES, ETC.

**Regular Army, Appointments.**—James L. Bevans, of Illinois, to be asst. surgeon, with the rank of first lieutenant.

**Retired for Disability Incident to the Service.**—Major Eugene L. Swift, surgeon, Dec. 9, 1901, under acts of Oct. 1, 1890, and Feb. 2, 1901.

**Volunteers, Honorably Discharged.**—Major Thomas U. Raymond, surgeon, Dec. 31, 1901; Captain Walter C. Childster, asst.-surgeon, Nov. 11, 1901; Captain Robert A. Anderson, asst.-surgeon, Nov. 16, 1901; Captain James H. McCall, asst.-surgeon, Dec. 31, 1901.

**Died.**—Captain John C. Orr, asst.-surgeon, Sept. 12, 1901.

### Navy Changes.

Changes in the Medical Corps of the Navy, for week ending Dec. 28, 1901:

P. A. Surgeon R. T. Orvis, ordered to the *Michigan* as the relief of P. A. Surgeon W. H. Grove.

P. A. Surgeon W. H. Grove, detached from the *Michigan* and ordered home to wait orders.

Pharmacist J. Cowan, ordered to the Boston Navy Yard.

Surgeon G. Rothganger, detached from the Naval Hospital, New York, and ordered to the *San Francisco*, January 2.

### Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, U. S. Marine-Hospital Service, during the week ended Dec. 27, 1901:

#### SMALLPOX—UNITED STATES.

California: San Francisco, Dec. 8-15, 1 case.  
Illinois: Chicago, Dec. 14-21, 2 cases.  
Indiana: Evansville, Dec. 14-21, 4 cases.  
Iowa: Clinton, Dec. 14-21, 2 cases.  
Louisiana: Dec. 14-21, New Orleans, 1 case; Shreveport, 5 cases.  
Massachusetts: Boston, Dec. 14-21, 41 cases, 12 deaths; Cambridge, Dec. 14-21, 3 cases; Gloucester, Dec. 14-21, 2 cases; Lowell, Dec. 14-21, 6 cases; Malden, Dec. 14-21, 3 cases, 1 death; Somerville, Dec. 13-20, 1 case.  
Michigan: Grand Rapids, Dec. 14-21, 1 case.  
Minnesota: Minneapolis, Dec. 7-14, 7 cases.  
Nebraska: Omaha, Dec. 14-21, 13 cases.  
New Hampshire: Nashua, Dec. 14-21, 1 case.  
New Jersey: Dec. 14-21, Camden, 15 cases; Newark, 24 cases, 12 deaths.  
New York: New York, Dec. 14-21, 12 cases, 1 death.  
Ohio: Ashland, Dec. 14-21, 1 case; Cincinnati, Dec. 13-20, 11 cases; Cleveland, Dec. 14-21, 1 case; Massillon, Dec. 7-14, 1 case.  
Pennsylvania: Lebanon, Dec. 14-21, 7 cases; Philadelphia, Dec. 14-21, 76 cases, 10 deaths.  
South Carolina: Greenville, Dec. 7-14, 2 cases.  
Tennessee: Memphis, Dec. 14-21, 2 cases.  
Utah: Salt Lake City, Dec. 14-21, 2 cases.  
Vermont: Burlington, Sept. 28-Dec. 21, 55 cases.  
Wisconsin: Green Bay, Dec. 15-22, 7 cases; Milwaukee, Dec. 14-21, 1 case.

#### SMALLPOX—FOREIGN.

Austria: Prague, Nov. 23-Dec. 7, 7 cases.  
Belgium: Antwerp, Nov. 23-30, 3 cases; Ghent, Nov. 30-Dec. 7, 3 deaths.  
Canada: Halifax, Dec. 7-21, 21 cases; St. John, Dec. 7-21, 11 cases, 2 deaths; Windsor, Dec. 14-21, 1 case; Winnipeg, Dec. 7-14, 4 cases.  
Colombia: Cartagena, Nov. 23-30, 2 deaths; Panama, Dec. 9-16, 25 cases.  
France: Paris, Nov. 30-Dec. 7, 1 case.  
Great Britain: Glasgow, Dec. 6-13, 4 deaths; Liverpool, Nov. 3-Dec. 7, 5 cases; London, Nov. 30-Dec. 7, 474 cases, 20 deaths.  
India: Calcutta, Nov. 16-23, 3 deaths; Madras, Nov. 15-22, 2 deaths.  
Italy: Naples, Nov. 23-30, 18 cases, 1 death.  
Russia: Moscow, Nov. 16-30, 23 cases, 9 deaths; Odessa, Nov. 23-Dec. 7, 22 cases, 3 deaths; St. Petersburg, Nov. 23-30, 8 cases; Warsaw, Nov. 16-23, 1 death.  
Spain: Corunna, Nov. 30-Dec. 7, 1 death.

#### YELLOW FEVER.

British West Indies: St. Lucia, Dec. 2-6, 8 cases, 6 deaths.  
Mexico: Vera Cruz, Dec. 1-14, 29 cases, 15 deaths.

#### CHOLERA.

Cuba: Havana, Nov. 29, 1 death from S. S. *Buenos Ayres*.  
India: Bombay, Nov. 19-26, 4 deaths; Calcutta, Nov. 16-23, 76 deaths; Madras, Nov. 15-22, 27 deaths.  
Straits Settlements: Singapore, Oct. 27-Nov. 2, 3 deaths.

#### PLAGUE—FOREIGN AND INSULAR.

India: Bombay, Nov. 19-26, 358 deaths; Calcutta, Nov. 16-23, 48 deaths; Karachi, Nov. 10-17, 71 cases, 49 deaths.  
Russia: Batoun, Nov. 30, 1 case.  
Turkey: Constantinople, Nov. 20-27, 1 case.  
Hawaii: Honolulu, Dec. 5, 1 death.

PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF PENNSYLVANIA.  
PHILADELPHIA.

Although our knowledge of the thermogenic mechanism is still in a formative state, we nevertheless have sufficient experimental data to warrant the conclusion that in the higher animals the heat formed arises in part as a product incident to the activities of all forms of vital processes, and in part as a specific product of specific heat-producing structures. The results of Rubner's researches leave no doubt as to the skeletal muscles possessing, besides their motorial properties, a specific thermogenic function, and, as a consequence, that these structures not only produce heat as an incident to repair, growth and motor activity, but also as a specific product. They further show that the quantity of heat which arises by virtue of this special function bears a reciprocal relationship to the amount formed as an incident to the activities of the body structures generally, increasing or decreasing in adjustment to the variations in thermogenesis caused by rest and activity, etc., and to the alterations in thermolysis which are dependent upon ever-changing internal and external conditions; so that as the output of heat incidentally produced increases or decreases, the quantity resulting from the specific thermal function of the skeletal muscles varies co-operatively in supplying the number of heat units required by the organism at any given time. Moreover, there can be no doubt that this specific thermal function is directly controlled by specific thermogenic centers, which are located in the cerebrospinal axis, although very little is known of their exact positions, functional relations and characteristics.

Since Tscheschichin<sup>1</sup> showed, thirty-five years ago, in an experiment upon a rabbit that injury of the base of the brain may be followed by a rapid and decided rise of body-temperature, considerable valuable information has been obtained from the researches of Bruck and Günter,<sup>2</sup> Eulenburg and Landois,<sup>3</sup> Hitzig,<sup>4</sup> Richet,<sup>5</sup> Wood,<sup>6</sup> Aronson and Sachs,<sup>7</sup> Girard,<sup>8</sup> Baginsky and Lehmann,<sup>9</sup> Baculo,<sup>10</sup> Ott,<sup>11</sup> White,<sup>12</sup> Tangl,<sup>13</sup> Kemp,<sup>14</sup> Schultz,<sup>15</sup> Schreiber,<sup>16</sup> and myself.<sup>17 18</sup> A critical study of these contributions justifies the following conclusions:

1. That specific thermogenic centers exist in the brain and spinal cord, and that these centers are connected with each other and with various parts of the body,

2. That the centers in the brain are either thermo-accelerator or thermo-inhibitory.
3. That the center in the spinal cord is a general or reflex center.
4. That the brain centers probably affect heat production by acting upon the spinal center.
5. That the spinal center when separated by section from the brain centers is able to maintain the normal standard of heat production.
6. That the activities of these centers is largely influenced by the changes in the temperature of the blood, and by cutaneous impulses which are probably generated in the peripheries of the "heat" and "cold" nerves.
7. That the caudate nuclei contain an important thermo-accelerator center.
8. That the pons and bulb probably contain a thermo-accelerator center.
9. That a thermo-inhibitory center is located in the dog in the first cerebral convolution posterior to and in the vicinity of the sulcus cruciatus, and that possibly another such center extends downward from the junction of the supra-sylvian and post-sylvian fissures to the posterior fissure.
10. That there is no adequate evidence to lead to the belief that specific heat centers exist in any other part of the body than in those above noted.

The experimental study of the locations and functional peculiarities of heat centers is attended by many sources of fallacy, some of which are unavoidable and some so important as to materially modify or even entirely vitiate the results. Shock, hemorrhage, the pressure of a clot, circulatory and respiratory disturbances, the involvement of contiguous parts, etc., may be more or less potent disturbing factors, but shock is pre-eminently the most important. The sensitivity of the cerebrospinal axis to injury is very evident in the more or less marked disturbances of temperature, which almost invariably follow, and which sometimes are decided and persistent. In some instances a rise continues until death ensues from the excessive temperature, and in others there occurs a steady and rapid fall, which progresses until there is general functional collapse. Shock causes the temperature to decrease, and its influences may be so powerful as to not only prevent the decided rise, which ordinarily would be caused by irritation of the caudate nuclei, but even to bring on at once a rapid decrease. The ease with which the body-temperature is affected by even trifling injuries of the brain makes it necessary to be very guarded in reaching conclusions as to the specific connection of any given portion of the cerebrospinal axis with the heat mechanism, unless the effects of shock, vaso-motor palsy, etc., can be eliminated to a satisfactory degree, and the results obtained by the section, puncture, ablation, etc., be reasonably uniform and positive.

In the experiments recorded in the present contri-

\* Read at the Fifty-second Annual Meeting of the American Medical Association in the Section on Physiology and Dietetics, and approved for publication by the Executive Committee: Drs. James Welr, Jr., Winfield S. Hall and Elmer Lee.

bution, essentially the same technique was pursued as in a preceding research<sup>12</sup> on the effects of lesions of the base of the brain upon the heat processes. Dogs were used and were thoroughly anesthetized with a mixture of ether and chloroform (3:1), a tracheal cannula was inserted, the skull was trephined on a level with the upper surface of the structure to be cut, and then a slightly bent, blunt-edged probe was pushed horizontally through the brain mass and withdrawn with a downward, sweeping movement, thus cutting all the nervous matter beneath, without, however, injuring any important vessels. Such section causes but trifling hemorrhage, and a variable amount of shock, which latter is indicated by immediate effects upon the respiratory movements and circulation, and in some cases by a fall of body-temperature. Artificial respiration was practiced throughout the experiments, even though it might have been possible for the ventilation of the lungs to have been carried on effectively by spontaneous respiratory movements.

When after the section a rise of temperature occurs, the result, eliminating any probable indirect effects due to the changes in the circulation and respiratory movements, is to be attributed to a cutting off of thermo-inhibitory impulses or to the generation of thermo-accelerator impulses. If due to the former, stimulation of the part of the brain involved in the section should lessen the temperature; while if the latter, the reverse. Inasmuch as section, puncture and other forms of stimulation of the striate bodies, crura cerebri and pons cause an increase of temperature, we are justified in the conclusion that the rise is due to an irritation of thermo-accelerator centers or nerves. In the research referred to it was found that sections of the striate bodies and pons were, as a rule, followed immediately, or within a few minutes, by a decided increase of temperature; and that section of the white matter anterior to the caudate nuclei, of the thalami, and of the crura cerebri, are either not followed by a rise or by one that is usually comparatively transient and not marked. The difference is such as to suggest that in the first instance thermo-accelerator centers were irritated, and in the other, thermo-accelerator fibers. Of 11 experiments in which the section was made of the striate bodies or pons, in 8 the increase of temperature ranged from 0.98 to 4.37; in 2 it was but 0.26 and 0.27, respectively; and in one the temperature fell. In one of the last 3, the section was 2 mm. posterior to the anterior extremity of the caudate nuclei and the effects of shock were greater than those of direct irritation of the thermo-accelerator cells; in the other 2 the animals suffered even more severely from shock, one dying within 45 minutes, and the other within 1 hour and 15 minutes. In a total of 24 experiments, in 2 of which the section was made through the white matter just anterior to the caudate nuclei, in 2 where it was made through the thalami, and in 20 through the crura cerebri, in 18 cases a rise was noted—in 12 of which it was transient—in 14 it was less than 1, and in only 4 was it over 1.

In another research<sup>13</sup> in which the sections were made of the spinal cord at the level of the first and second cervical vertebrae, in 9 out of 10 experiments the temperature fell from the first. Probably the vasomotor palsy necessarily caused by these sections is almost solely accountable for the decrease. When sections are made of the bulb the effects are variable, and depend largely upon the extent to which the vasomotor center is involved, a fall of temperature occurring if the center is seriously affected, and a rise if not. If a rise occurs it is rarely

so decided as when the section is through the pons; and the temperature curves differ in other respects. These experiments show, in a word, that sections of the caudate nuclei and pons are followed by results which, as a whole, differ materially from those caused by sections of other portions of the cerebrospinal axis at any point between the white matter anterior to the striate bodies and the level of the first and second cervical vertebrae, and they are such as to indicate that thermo-accelerator centers are located both in the caudate nuclei and ponto-bulbar region.

The main results of the research (*loc. cit.*) upon the effects of sections of the basal parts of brain are summarized in the following table.

TABLE 1.—Summary of the chief results of the sections anterior to the striate bodies, striate bodies, thalami, crura cerebri and pons.

|                                     | Number of experiments. | Mean maximum rise of temperature. Degrees. | Mean time of occurrence of maximum rise of temperature. hrs. min. |
|-------------------------------------|------------------------|--|---|
| Sections anterior to striate bodies | 2                      |  |   |
| Sections of the striate bodies.     | 2                      | 2.4  | 2.53  |
| Sections of the thalami             | 2                      | 0.12                                       | 5   |
| Sections of the crura cerebri       | 20                     | 0.8  | 1.20  |
| Sections of the pons                | 3                      | 2.74                                       | 4   |

The studies made by various investigators of the thermal functions of the caudate nuclei are more numerous, extensive and convincing than those of the ponto-bulbar region, and the results are sufficient to justify the belief that these structures contain an important thermo-accelerator center. As to the ponto-bulbar region, the data upon which rests the belief that it contains a thermo-accelerator center is to be found mainly in the reports of the experiments by Tscheschichin,<sup>1</sup> Bruck and Günter,<sup>2</sup> Wood,<sup>3</sup> Ott,<sup>14</sup> and myself (*loc. cit.*). But little intrinsic value is attached to the results obtained by Tscheschichin, Bruck and Günter, and Ott. Tscheschichin found in a single experiment upon a rabbit, in which the pons was severed from the bulb, that the temperature rose from 39.7 to 41.2 (1.5) in 30 minutes. Bruck and Günter in 23 experiments upon rabbits, in which the ponto-bulbar section of puncture was practiced, noted an increase in 11. Ott in 10 experiments on rabbits, in which the pons was punctured at various points, recorded in 6 a transient rise, usually slight and ranging from 0.3 to 2.6; in the other 4 the temperature fell. In Wood's research upon dogs and rabbits it was found that "injuries of the medulla so situated as to paralyze the medullary vasomotor center, are followed by a decided fall of animal temperature: section of the medulla at the line of its junction with the pons in the dog, usually leads to an elevation of animal temperature, if the medullary vasomotor centers are not in any way impaired; section of the medulla at its junction with the pons is followed by increased heat dissipation and increased heat production, the increased heat dissipation usually not keeping pace with the increased production, so that the body temperature rises." In three experiments on dogs, in which the section—at the junction of the pons and bulb—was complete, the rises of temperature amounted to 3.25 in 1 hour and 30 minutes, 4.88 in 2 hours and 35 minutes, and 3.88 in 5 hours and 25 minutes. In 4 experiments in which the sections were incomplete, 2 being on dogs and 2 on rabbits, in 3 the section was at the junction of the pons and bulb and in one through the pons, an increase of temperature was observed in each, but the greatest rise was only 1.1.

In other experiments in which the sections were made lower in the bulb the temperature invariably fell, owing probably to the serious involvement of the vasomotor center. In my own experiments (*loc. cit.*) in which special studies were made of the temperature alterations in five dogs after the complete transverse section of the pons, in one the animal lived for less than an hour, and the temperature fell steadily from the time of the section, evidently because of severe shock; in the other four the rises were 3.48, 0.27, 2.87, and 4.34, respectively. In the experiment in which a rise of only 0.27 was recorded, the animal died within 1 hour and 15 minutes after the operation, the smallness of the rise probably being due to shock. In two calorimetric experiments the increases were 0.61 and 0.76, but these figures do not in all probability represent the highest points reached. In one of them the section was obliquely through the middle of the pons, and in the other through the point of union of the pons and bulb. The results show, in accord with Wood's, that the increase of temperature caused by pontine section is due to an increase of heat production.

This research I have supplemented by over 20 experiments upon dogs, but I have included in the present article only the records of those experiments in which autopsies showed that the *sections were complete*. The levels of the sections varied from the middle of the crura cerebri to within 3 mm. of the junction of the bulb and spinal cord. The detailed records of these experiments will be found in the accompanying tables, which also include a number from the earlier research. In the selection of the latter, only those experiments have been chosen in which the animals lived for at least two hours after the operation. When death occurred within this period, the effects of shock robbed the results of most of their value, especially for purposes of comparison of the effects of lesions of different localities upon the heat functions. The experiments are appropriately divided into four groups in accordance as the sections were through the caudate nuclei, crura cerebri, pons or bulb.

1. *Experiments in which the sections were through the caudate nuclei.*—In 6 experiments in which the level of the section varied from 2 mm. to 12 mm. from the anterior extremity of the nuclei, an increase of temperature was recorded in each (Table 2). In No. 1 it was only 0.26 and very transient, and was followed by a steady decrease for 4 hours and 15 minutes, when the experiment was ended. The section was 3 mm. from the anterior end. In the other 5 cases the rise amounted to 0.98, 4.37, 2.25 and 2.2, respectively. The average, which is 2.4, may properly be taken as approximately representing the mean maximum increase caused by the section of the nuclei at different levels as far back as 12 mm. The average time of the occurrence of the maximum increase was 2 hours and 53 minutes; in experiments 3 and 4 the maxima had not probably been attained at the time the experiments were concluded.

2. *Experiments in which the sections were through the crura cerebri.*—In 13 experiments in which the sections varied from a level close to the optic thalami to within 3 mm. of the pons, in 10 a rise occurred (Table 3). The increases were 0.04, 2.94, 1.2, 0.12, 0.4, 1.1, 0.82, 1.30, 3.64 and 0.62—the minimum was 0.04, the maximum was 3.54, and the average, 1.22. The average time of the occurrence of the maximum rise was about 3 hours, the shortest being 10 minutes, and the longest 7 hours and 30 minutes. In seven experiments the maximum was reached within three hours.

### 3. Experiments in which the sections were through

*the pons.*—Ten experiments were made in which the pons was severed at points varying from the tip of the anterior extremity to the posterior edge (Table 4). In every one a rise occurred, varying from 1.3 to 4.86. The maxima were 3.48, 2.87, 4.34, 3.54, 4.83, 3.12, 1.3, 4.5, 4.43 and 4.86; the average increase was 3.73. The time

of the occurrence of the maximum increase varied from 2 hours and 45 minutes to 7 hours, the average being about 5 hours. In 7 experiments the observations were continued from 5 to 7 hours, and in 3 they lasted for

from 2 hours and 45 minutes to 3 hours and 37 minutes. It is to be noted that in every experiment but 2—Nos. 20 and 29—the temperature was still rising when the experiments were concluded. The mean increase of temperature in this series was not only more marked, but steadier and more persistent than in the previous series.

#### 4. Experiments in which the sections were through

TABLE 5.—Records of 6 experiments in which the sections were through the bulb.

| Number of experiment.                                   | 30                 | 32                 | 32                   | 33                   | 34                   | 35                          |
|---|--------------------|--------------------|----------------------|----------------------|----------------------|-----------------------------|
| Level of the section.                                   | Close to the pons. | Close to the pons. | 2 mm. from the pons. | 2 mm. from the pons. | 6 mm. from the pons. | 3 mm. from the spinal cord. |
| Time after the section. hrs. min.                       | Deg.               | Deg.               | Deg.                 | Deg.                 | Deg.                 | Deg.                        |

the bulb.—In 7 experiments the sections were through the bulb at different levels. In 2 the temperature increased steadily for over 5 hours; in one the rise was 0.68 and in the other it was 2.59 (Table 5). In the remaining 5 there occurred a slow, steady fall, which in 3 cases continued until death, and in one slightly recovered after the lapse of 4 hours and 15 minutes. In the 2 experiments in which the rise occurred the sections were in each 2 mm. from the pons. Sections of the bulb must necessarily seriously affect the vasomotor center, and it is noteworthy, when it is remembered how rapid

TABLE 6.—Summary of main results of the sections of the caudate nuclei, crura cerebri, pons and bulb.

|                                 | Number of experiments | Number in which a rise of temperature occurred. | Number in which a rise of temperature did not occur | Average maximum rise of temperature. Degrees | Average time after the section of the maximum rise of temp. |
|---------------------------------|-----------------------|---|---|--|---|
| Sections of the caudate nuclei. | 6                     | 6   | 0   | 2.4  | 2 hr. 53 min.   |
| Sections of the crura cerebri.  | 13                    | 10  | 3   | 1.22   | 3 hr.   |
| Sections of the pons . . .      | 10                    | 10  | 0   | 3.73   | 5 hr.   |
| Sections of the bulb . . .      | 7                     | 2   | 5   | 1.64   | 6 hr.   |

is the fall of temperature caused by vasomotor palsy, that a rise of temperature ever occurs under such conditions. The most important results of these 4 series of experiments are summarized in Table 6.

A study of the results of these experiments shows that the effects caused by the sections of the caudate nuclei, crura cerebri, pons and bulb are in each case, as a whole, quite characteristic, and that thermo-accelerator centers certainly exist in both the caudate nuclei and the ponto-bulbar region. There can be no reasonable doubt that the cause of the rise of temperature when the caudate nuclei are injured is to be found essentially or solely in an excitation of a thermo-accelerator center, because similar irritation of parts in front of, above and beneath do not give rise to any notable increase of temperature, as should be expected if the nuclei merely represented a pathway of thermo-accelerator fibers which run to or from these parts. Starting then with the caudate nuclei as a point of origin of efferent thermo-accelerator fibers, it is evident that in order to directly or indirectly reach the thermogenic tissues they should be found running through the crura cerebri, pons and bulb into the spinal cord, and that their irritation at any point along this course might be followed by an increase of temperature providing that shock, vasomotor disturbances, etc., do not interfere; and, moreover, that irritation of this thermo-accelerator pathway should cause a less marked increase than when the thermo-accelerator center itself is irritated. A comparison of the figures which illustrate the main results of caudate and crura sections (Table 6) will show that in every one of the caudate experiments a rise of temperature occurred, while in only 10 of the 13 crural experiments was there an increase; and that the increase caused by caudate section was about double that following the section of the crura. The less marked and less rapid rise after crural section is logically to be attributed to one or more of three factors: 1, to the coincident irritation of hypothetical thermo-inhibitory fibers, which run from the cortical centers to the pons and parts below; 2, to the probably more marked vascular disturbances due to the section being nearer the cardiac and vasomotor centers, and 3, to the probable absence of thermo-accelerator cells from the crura. It is by no means likely that the irritation of thermo-inhibitory fibers has any important effect; while kymograph records show that the circulatory disturbances, although more marked as a rule the nearer the section to the bulbar centers, are not sufficient to explain the smaller rise caused by crural section. It seems therefore justifiable to assume that the increase of temperature caused by the section of the crura is due to the irritation of the thermo-accelerator fibers, and that the rise is less marked than when the caudate nuclei are irritated, chiefly because of the absence of thermo-accelerator cells in the former.

This view receives additional support in the results of the experiments in which the sections were made through the pons and upper part of the bulb. In pontine section, as in section of the caudate nuclei, an increase of temperature was not only invariably observed, but it was generally more marked and much more persistent than after sections of the latter, notwithstanding the nearness of the section to the vasomotor center, and the consequent vasomotor weakness and resulting rapid heat loss. The differences in the temperature effects caused by injuries of these two bodies can not apparently satisfactorily be explained except by admitting, as previously stated, the existence of a thermo-accelerator center in the pons and bulb, and that this center is even more powerful than that in the caudate nuclei. In fact, the center must be more potent than is indicated by the actual temperature records, because the rise was undoubtedly more or less

interfered with by the effects of the depression of the vasomotor center. That the center extends for some distance in the bulb is rendered probable by the fact that a marked rise of temperature may still be observed when the section is close to or at the junction of the pons and bulb. In several experiments in which the lobes cerebellum or the cerebellar peduncles were cut, no temperature changes were in any case noted which were at all comparable to those caused by pontine section.

Not only do the mean rises in temperature vary in degree in accordance with the region affected, but the temperature curves exhibit distinct characteristics, and such as to indicate the organ involved. Thus, after section of the caudate nuclei, the temperature tends to increase for approximately three hours on an average and then subside. In the sections of the crura cerebri the mean maximum rise is reached in about the same time, but the temperature curve rises only half as rapidly. In the pontine experiments the rise is not quite

Chart of temperature curves during first three hours after the sections. The broken line is the temperature curve of the caudate series; the unbroken line of the pontine series; and the dotted line of the crural series.

so rapid as in the caudate series, but there is a marked tendency to a steady increase for from 6 to 7 hours or more, or until fatal hyperpyrexia is established. These differences can be better appreciated by a glance at the accompanying chart in which are exhibited composite temperature curves of the caudate, crural and pontine experiments. The marked differences in the mean temperature curves of the caudate and pontine sections indicate that the thermo-accelerator centers in these structures differ at least in power—the latter being the stronger—if not in other important features. That they are functionally different has been shown conclusively in experiments in which I have injected powerful pyretics and antipyretics in large doses after the sections. For instance, after section of the caudate nuclei, and after section of the crura cerebri, the administration of cocain and morphin has no effect upon the temperature changes caused by the section: cocain neither increases the rise nor hinders the fall; nor does morphin hinder the rise or hasten the fall, unless given in such quantities as to seriously affect the circulation, etc. It seems

from this that the direct action of both cocain and morphin upon the heat mechanism is upon the thermo-accelerator center in the caudate nuclei. This subject has, however, so important a bearing upon febrile processes, and is of such scope, that a further consideration must be left for a special article.

#### DISCUSSION.

DR. R. O. BEARD, Minneapolis—Referring to Dr. Reichert's conclusions I would suggest a possible source of error in his sections arising from the stimulation incident to section of afferent as well as efferent fibers related to the thermotaxic centers. The fillet from the ascending lateral tract of Gowers, which is believed to carry impressions of temperature to these centers, passing upward through the bulb and pons, might easily be involved in Dr. Reichert's pontine and bulbar sections; while lying in the lateral fillet, beyond the pons, it might escape in his sections of the crura. Section has always been a doubtful method of localizing centers.

#### PERNICIOUS ANEMIA—THE STATISTICS OF A SERIES OF FORTY CASES.\*

THOMAS McCRAE, M.B., M.R.C.P.

Associate in Medicine, the Johns Hopkins University; Resident Physician, the Johns Hopkins Hospital.

BALTIMORE.

This paper is a report of a series of 40 cases of pernicious anemia which have occurred in the service of Dr. Osler in the Johns Hopkins Hospital. No attempt will be made to discuss in any detail the features of the disease or to give any extended notes of the histories of the patients. Cases in which there was any doubt as to the diagnosis have not been included. These 40 patients were among approximately 12,500 general medical admissions.

**Incidence.**—There were 32 males and 8 females, a rather unusual ratio for which no explanation can be given. The general admissions are about 5 males to 4 females. Large series show little difference in the number from each sex. As to age, the distribution was: 1 to 10 years, 1 case; 11 to 20, none; 21 to 30, 7 cases; 31 to 40, 6 cases; 41 to 50, 13 cases; 51 to 60, 7 cases; 61 to 70, 6 cases. It will be observed that four-fifths of the patients were over 30 years of age. The youngest was aged 10 and the oldest 66 years. In regard to race there were only 2 colored patients in the series, a proportion of 1 to 19, while the general ratio of admissions is about 1 colored to 7 white patients.

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee of the Section: Frank Billings, George Dock and J. M. Anders.

**Etiology.**—There seemed but little of importance found in regard to this. In only one of the females did a previous confinement seem in any way connected with the onset. Mental distress and worry did not figure to any extent, there being only 3 patients who gave a history of these, although an unusual number of them were in the private wards. There was a tuberculous family history in 7 cases. Four had a history of syphilis and 14 of malaria. Previous stomach trouble had occurred in 5 and 12 had used alcohol. In one the onset followed a severe carbuncle. In the earlier cases the condition of the mouth was not noted carefully, but in the last 10 cases, carious teeth or some septic process in the mouth occurred in only 4 instances.

**Complaint.**—It is of interest to note the symptoms of which the patients themselves made complaint. The largest number, namely, 23, complained principally of weakness. In 11 the gastric and bowel symptoms were most marked. Four came only on account of nervous manifestations; 2 complained of the discoloration of the skin.

**Onset.**—The first symptom noted was weakness in 14 of the series. Weakness associated with some other condition in 9, dyspnea in 9, and digestive disturbances in 8 instances.

**Symptoms.**—In the histories given by the patients, of the symptoms mentioned especially, weakness was most frequent, namely, in 26 cases, change of color in 25, loss of weight in 22—a rather surprisingly large number as the usual description of the disease lays emphasis on the absence of emaciation—and shortness of breath in 16 cases. Digestive disturbances with diarrhea were present in 11 and gastric symptoms alone in 8 instances. Hemorrhages from the mucous membranes had occurred in 9 cases, and in 8 there had been some edema. Of the nervous manifestations, 4 gave a history of various sensory conditions usually tingling and numbness, one of severe pain, one of paraplegia, one of mental changes, and five of varied symptoms such as difficulty in walking, stiffness of the legs, etc.

**Examination.**—Of the conditions found the following were the most important. Marked emaciation was noted in 10 instances. The typical lemon-yellow color was observed in 29, and in 7 there was marked pallor without any special yellow tint. Pigmentation of the skin apart from the general discoloration was present in 8 and in 4 petechiæ were found.

In the circulatory system there was marked visible pulsation of the vessels in 16 cases. An apex systolic murmur was heard in 15, a systolic murmur everywhere over the heart in 13, and in one instance a systolic murmur was heard only in the pulmonic area. A loud systolic bruit was heard over the vessels of the neck in 12, and in 5 the complete absence of any such murmur was noted. In the examination of the abdomen, the liver was only felt in 2 instances. The spleen was felt in only 6 cases and in none of these was the enlargement at all marked, it being noted in all that "the spleen was just felt." There was marked general glandular enlargement only in 3 cases, and in 5 the majority of the glands were enlarged. Hemorrhages from the mucous membranes occurred in 8 patients during their stay in the hospital. Edema was present in 7 cases. As already noted, only in 4 out of at least 10 cases was a specially septic condition of the mouth noted.

The temperature was practically normal throughout their stay in the hospital in 10 of the series. In 27 it was more or less elevated, in 20 of these the average

elevation being about 101, while in the remaining 7 it varied from 101 to 106. Three were under observation for too short a time to obtain continued records. The urine was free from albumin in 23 cases. In the remaining 17 it was present, but only in very slight amounts. In no instance was sugar found. The reaction in 37 was acid, in one neutral and in 2 alkaline. The specific gravity in 10 was below 1010, in 24 between 1010 and 1020, and in 5 between 1020 and 1030.

While the patients were under observation the gastrointestinal symptoms were as follows: As regards the stomach, in 22 there were no disturbances of any kind; of the remaining 18 the symptoms were slight in 14 and grave in 4 instances. The bowels were normal in 16 cases, constipation was present in 14, diarrhea in 8 and alternating constipation and diarrhea in 2 instances.

Nervous manifestations were present in 10 instances. These varied from sensory disturbances alone to complete paraplegia. The cases showed so many differences that it was found impossible to classify them under any definite headings. The prevailing type was one with some sensory disturbances, especially in the extremities, associated with a more or less marked spastic condition. There was complete paraplegia in one, loss of power over the bladder in one, and marked incoördination with absence of the knee-jerks in one instance. Some degree of incoördination was frequently found. In some of the patients the nervous symptoms progressed while they were under observation, but in others some improvement was noted.

**Blood.**—Full counts were obtained when they first came under observation in 36 patients. The average of these was: Hemoglobin, 30 per cent. (von Fleischl): red corpuscles, 1,560,000 per c.mm.; white corpuscles, 6929 per c.mm.

Complete differential counts<sup>1</sup> were made in 30 of these, the average of the series being: Polymorphonuclears, 61 per cent.; small mononuclears, 31 per cent.; large mononuclears and transitionals, 4 per cent.; eosinophiles, 2 per cent. There were small numbers of myelocytes found in some of the cases, but never any marked percentage; the average was less than 1 per cent.

The average number of nucleated red cells found in counting 1000 leucocytes was 37. Of these the average of each variety was: Normoblasts, 23.4; megaloblasts, 4.7; intermediate forms, 9.4.

These figures are for the series of 30 cases. But among these there were three cases in which nucleated red cells occurred in very large numbers, namely, 262 (of which 222 were intermediate forms), 124 (of which 120 were normoblasts) and 420 (all of which were normoblasts) per 1000 leucocytes. If these three rather unusual cases be removed from the series, the average number of nucleated red cells per 1000 leucocytes for the remaining 27 cases is 12.7, and of these there were of normoblasts, 6; megaloblasts, 4.7; and intermediate forms, 2.

It is of interest to compare the differential counts in the fatal cases with those in the cases discharged improved. There were 11 of the series with a fatal termination. The relative percentages are the following:

|                                   | Death (11). | Improved (19). |
|-----------------------------------|-------------|----------------|
| Polymorphonuclears .....          | 62          | 61             |
| Small mononuclears .....          | 29          | 31             |
| Large do. and transitionals ..... | 4           | 4              |
| Eosinophiles .....                | 2           | 2              |

1. For this as a routine, Ehrlich's triple stain was used. The classification of the leucocytes is that of Ehrlich. The fractions or percentages are not given.

The average number of nucleated cells per 1000 leucocytes along with the number of each variety was:

|                     | Death | Improved |
|---------------------|-------|----------|
| Nucleated red cells | 23    | 47       |
| Normoblasts         | 7     | 34       |
| Megaloblasts        | 11    | 1        |
| Intermediate forms  | 4     | 12       |

If, however, the three cases referred to before with the large number of nucleated red cells—all of which were discharged much improved—be subtracted from that series, we obtain very different figures, namely, an average per 1000 leucocytes of only 6.8 nucleated reds in the cases that improved, of which there were: Normoblasts, 5; megaloblasts, 7; intermediate forms, 1.

It will be noted that the average percentage of small mononuclears was lower in the fatal cases than in those that improved. This is contrary to the generally accepted view that a high percentage of these cells is of unfavorable prognostic importance. This also meant a lower absolute number of small mononuclears, as the average leucocyte count in the fatal cases was lower than in those that improved. There is also a striking difference in the average number of the nucleated red cells per 1000 leucocytes found, namely, 23 in the fatal to 7 in the non-fatal (if the three cases before mentioned be left out of the average). The variation in the relative ratios of the various forms is marked. The normoblasts comprise only 33 per cent. of all nucleated forms in the fatal and 73 per cent. in the ones that improved. The megaloblasts were 48 per cent. in the fatal and 14 per cent. in the non-fatal series. The percentage of the intermediate forms in the fatal cases is 17 per cent. to 14 per cent. in the non-fatal series. This rather suggests that as regards prognosis no special conclusion can be drawn from their occurrence.

There were 16 cases in the series with the counts of the red corpuscles below one million per cubic millimeter. Of these twelve died in the hospital. Of the remaining four, one apparently recovered completely and was admitted six years afterwards with cancer of the stomach, a second has lived for over three years and is in fairly good condition at present, while the other two can not be traced. In no one of these four cases did the red count fall below 900,000 per c.mm. In two of the fatal cases the last count before death was over one million red cells.

**Results.**—Death occurred in the hospital or shortly after discharge in 17 of the series. The average duration of these was practically twelve months. Eight of them, however, ran the whole course in less than six months. Fourteen were discharged improved; one of these apparently recovered completely; one was followed for four years; one is alive nearly six years afterwards, and another three years afterwards. Seven were discharged unimproved and two were not treated. The average duration of the non-fatal cases was sixteen months at the time of their admission. Twelve of these patients made substantial gains in weight. The nervous symptoms showed varying results; some progressed while under observation, and others showed gain. There was no uniformity in their course.

**Treatment.**—This may be alluded to briefly. It consisted generally of absolute rest in bed, fresh air, abundant good food, and arsenic. Attention was paid to the condition of the mouth, especially in the later cases. Conditions arising in the course of the disease were treated symptomatically.\*

## THE PHARMACOLOGY OF THE SUPRARENAL GLAND AND A METHOD OF ASSAYING ITS PRODUCTS.\*

E. M. HOUGHTON, Ph.G., M.D.

Lecturer on Experimental Pharmacology, Detroit College of Medicine.

DETROIT, MICH.

Addison was the first, in 1855, to point out the great importance of the adrenals to the animal economy, showing that the disease now bearing his name was due to lesions, usually tuberculosis, of these bodies. The following year Brown-Séquard demonstrated experimentally that these glands: "1, are essential to life; 2, that they modify or destroy a substance which otherwise transforms itself into pigment; 3, that when the organs are destroyed or removed this substance collects in the blood; 4, that removal is rapidly fatal, and injection of the blood of an animal thus treated into a healthy animal leads to symptoms like those of removal." Gratiolet, Phillipeaux and Harley disputed these findings, but Brown-Séquard by another series of experiments showed that his previous conclusions were correct. Brown-Séquard's conclusions were a little later confirmed by Tizzoni. Vulpian and Virchow also in 1856 showed that a reducing agent was contained in the medulla of the suprarenal bodies, which has been observed by all subsequent chemical investigators.

Arnold, in 1866, obtained a crystalline body, but this could not be confirmed in the following year by Holm. Krukenberg, in 1885, showed that the color reactions were possibly due to pyrocatechin. This was confirmed by Brunner in 1892. Marino-Zucco, about the same time, obtained considerable quantities of neurin from these bodies, while Dutto found that neurin was present in the urine of patients suffering from Addison's disease. Marino-Zucco and Guaruceri in a later series of papers were able to show more conclusively that neurin was the toxic agent present. Moore, in 1894, made an extensive chemical study of the question and showed that the blood pressure raising substance contained in these glands was likewise the chromogenic substance of Vulpian. Fraenkel, in 1896, obtained a possible pyrocatechin derivative which he names "sphygmogenin." Moore disputed his findings and concluded that the active substance was a pyridin derivative. The same year Muhlmann, however, obtained a pyrocatechin compound. Abel likewise, in 1896, published the first of a very important series of papers in which he described a number of crystalline compounds, giving their chemical and pharmacological properties, which he had succeeded in isolating from the suprarenal glands. He concluded that the active substance was of the formula  $C_{17}H_{15}NO_4$ , and named it "epinephrin." Von Furth isolated a substance the following year, calling it "suprarenin," which he supposed to be different from epinephrin. Takamine and Aldrich, working independently in different laboratories on the question last year, referred to me about the same time for pharmacologic examination crystalline compounds which they had obtained from these bodies, which are extremely active and are probably identical, as shown by Aldrich. The name "adrenalin" has been given to the product obtained by Takamine.

Pellacani, in 1874, reported the results of some ani-

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. Thomas Hunt Stucky, Leon L. Solomon, and N. S. Davis, Jr.

mal experiments, ten years later giving a more detailed report on the subject in conjunction with Foa. These investigators injected subcutaneously and intravenously into dogs, guinea-pigs and rabbits, varying sized doses of a filtered aqueous extract of these organs. Often the animals showed no symptoms at the time of the subcutaneous injection, but were found dead the following day; others showed more or less muscular prostration and paresis; some vomited and developed symptoms of dyspnea, and apparently a few of the animals died from respiratory paralysis. Intravenous injections produced besides respiratory symptoms, at first quickening, later slowing and weakening of the heart, some of the animals becoming partially paralyzed; they found likewise that extracts of liver and kidney produced death when administered in the same manner. The results of their experiments were of little value, as shown by Alexander, Mattei and later workers. Langlois and Abelous showed that the toxemia produced by removal of these glands could be prevented by the injection of extracts of healthy glands, and that the injection of blood from acapsulated animals produced results similar to those following removal.

Several theories have been proposed to explain the function of the suprarenal glands, the most plausible being that they form a substance of vital importance to the animal economy; another receiving but little support is that an antitoxin is elaborated which neutralizes various toxic substances produced in the body. Oliver and Schafer, in 1894, published the first of a series of papers which shed much light on the subject. They support the former of these theories, finding that extracts of the medullary portion of these bodies exert a marked influence upon the striped and unstriped muscles; and produce great increase in blood pressure, from their stimulant action on the heart, blood vessels and centers in the medulla. Negative results were obtained from extracts of glands obtained from cases of Addison's disease.

Gottlieb concluded from his investigations that the active substance of the suprarenal gland increased the heart's action by stimulating the cardiac motor ganglia. He found that injection of the extract with compression of the thorax would cause the heart which had stopped beating from chloral hydrate to recommence pulsating. This fact, which has been confirmed by Radziejewski, may be of much therapeutic importance. Howell has shown that the adrenal vein contains more of this active secretion than other veins of the body. Biedl, in 1896, found that the blood pressure is enormously increased from the injection of suprarenal extracts even after section of the medulla and destruction of the spinal cord. Cleghorn showed upon the isolated mammalian heart that an extract of the adrenals produced a great increase in the force of the contractions, while similar extracts of other animal tissues had but slight influence. Wallace and Mogk found that suprarenal extracts produce a marked rise in the systemic blood pressure by contraction of the arterioles, no rise occurring in the pulmonary circulation; the heart is slowed from vagus stimulation; the heart muscle is directly stimulated, resulting in an increase in the number and force of its contractions, and that the entire action of the drug is a very fleeting one and passes off in from one to ten minutes. Hunt showed last year that suprarenal extracts contain a substance which produces lowering of blood pressure when injected into the circulation, but since the blood pressure is always greatly raised by even very minute quantities of

fresh preparations, it is probably of little practical importance therapeutically.

As I pointed out last year in a paper before this Section, the rise in blood pressure varies with the amount of the active substance injected intravenously. This reaction is so constant, as shown by hundreds of experiments since the former paper was written, that it has been found, as will be shown subsequently, a very valuable means of determining the amount of active substance contained in a given preparation.

We may briefly summarize our knowledge of the pharmacologic action of the various preparations of the suprarenal gland as follows:

Transient paralysis is observed in frogs when extracts of the suprarenal or its active principle are injected into the abdominal lymph sac and death may result, if the dose be sufficiently large.

Bates, who first proposed the use of the suprarenal gland for therapeutic purposes, is of the opinion that it serves as a useful heart tonic when administered *per os*, but it is doubtful, judging from the results obtained in the laboratory, if sufficient quantities are ever absorbed from the alimentary canal to produce symptoms of its action. When large doses are injected subcutaneously into dogs, guinea-pigs, etc., local irritation sometimes followed by suppuration is noticed. If sufficient quantities are absorbed, excitement followed by paresis of the hind limbs, accelerated respiration and dyspnea are often noticed, and death from respiratory failure occurs. I am having a series of experiments made to determine the best methods of administration. Extremely small quantities of fresh extracts, epinephrin or adrenalin, when injected intravenously, produce almost instantly marked rise in blood pressure with slowing and strengthening of the heart beats. This rise in blood pressure is due mainly to contraction of the muscular coat of the arterioles from the local action of the substance on their walls, as is shown by perfusion experiments on frogs, etc., the stimulation of the heart muscle itself and the stimulation of the vasomotor center. The slowing of the heart is due to stimulation of the vagus center. The heart muscle cells are stimulated, the systole becoming more complete while the diastole is less perfect. In fact, except for the very fleeting influence on the circulation one might compare the action of the suprarenals to that of digitalis.

Preparations of the suprarenal gland and its active principle have been employed for numerous purposes. It has been applied with marked success as a local hemostatic to nearly all parts of the body, to prevent hemorrhage during operations, to check postpartum hemorrhage, hemorrhage from the stomach, to allay local inflammation, etc. Injected into the vein or the heart in cases of collapse during anesthesia is one of the latest suggestions; in extreme cases this may be of much importance, as unlike the digitalis series of heart tonics its toxic action is very slight.

Until recently the dried and powdered glands with or without milk sugar were the products generally employed in therapeutics. Frequent attempts were made to exhibit a liquid preparation, but it was necessary to add some antiseptic, as thymol, boracic acid, chloretone, etc., to prevent decomposition. Since we have no chemical means for assaying these products, it seemed advisable to work out a physiological method that could be readily employed by manufacturers to determine the strength of their products. As the result of investigation along numerous lines, the following method, which

is based on the sub-maximum blood pressure obtained by injecting intravenously the preparation, dissolved in water having removed the inert material as far as possible, and comparing the blood pressure tracings obtained with those obtained from the same animal by injecting a known quantity of a preparation of standard activity, has given me the most satisfactory results.

Hypodermic syringes, surgical instrument of various kinds, small glass canulae, and a large sized sphygmograph, with manometer arranged for taking blood pressure

to obtain detailed results. (See tracings Nos. 1 and 2). However, usually abbreviated tracings (See tracings Nos. 3 and 4), which gives only the maximum blood pressure obtained from each injection are quite sufficient.

Various animals may be employed, but dogs of medium size give the best results. In any case the animal should be completely anesthetized. Since it is of great importance that the blood pressure does not fluctuate from the action of the anesthetic, I always employ

No. 1—Complete tracing showing variations in the blood pressure from the intravenous injection of different amounts of adrenalin.

No. 2—Complete tracing showing action on heart (above) and blood pressure (below).

No. 3—Abbreviated blood pressure tracing

No. 4.—Abbreviated blood pressure tracing showing the comparative action of two solutions of adrenalin. The solutions were of exactly the same strength, but the person making the assay supposed they were of different strengths until he had proven by experiment that they had the same influence on blood pressure.

No. 5—Abbreviated tracing showing the comparative action of two solutions of adrenalin of different strengths.

tracings, or continuous ones or shorter ones, are required. The paper, whether smoked or not, should have linear markings 5 cm. or less apart, for convenient reading the results. Two kinds of tracings may be obtained, complete ones, where the drum is kept in constant motion, and abbreviated ones where the drum remains at rest until the reaction is complete. If a carbon paper is employed, one or more sheets will be necessary

therefore given per os, instead of chloroform or ether for this purpose. Also because of the long-continued action and ease of administration, chloroform is especially valuable for this work, as the blood pressure and action of the heart remain constant for many hours.

After the animal is anesthetized the hair is clipped from the throat, the tissues severed and a glass canula of suitable size is tied in the common carotid artery,

which in turn is connected with a tube filled with half saturated sodium carbonate solution, to prevent the blood from clotting, leading to the manometer. The solutions—adrenalin or preparations from the suprarenal gland—for injection should be very carefully prepared, and of such a strength that they can be readily diluted in case the primary injection is found to produce too marked a rise in the blood pressure. The injections may be made either in the jugular vein or into the femoral vein, preferably the latter. As will be noticed from tracing (No. 5) an injection of the preparation that is being assayed is preceded or followed by the injection of a known quantity of a standard preparation. Sufficient time should be allowed after each injection for the blood pressure to return to the normal. The two tracings are compared, and in case the increase in pressure is not the same the solutions should be so diluted that the increase in pressure is the same, but in each case less than the maximum height. In no case, however, should a conclusion relative to the strength of a preparation be reached from the results obtained from a single animal; usually three should be employed. The animals, of course, are destroyed as soon as the experiment is completed.

At first I employed a freshly-prepared aqueous extract, 1 c.c. representing 1 gram of the fresh suprarenal gland as a standard. However, since the standard in this case varied somewhat in strength, because of oxidation, decomposition, variable amounts of blood-lowering principle, etc., the results were not entirely constant. Some months after commencing these studies, Drs. Takamine and Aldrich each supplied me with a crystalline product from suprarenal glands, which, on comparing its activity with the freshly-prepared aqueous extract, proved to be from 600 to 800 times as strong, and since it does not undergo deterioration, I have adopted it as a standard for assaying other preparations. Usually this active principle, adrenalin, is made up in solution of 1 to 10,000, a trace of hydrochloric acid being added, the same amount of hydrochloric acid being added also to the aqueous solution prepared for test purposes from the preparation which is to be assayed. It is of paramount importance in employing this method to keep the conditions during the experiment always constant.

One of my assistants, assaying unknowns prepared from adrenalin, obtained the following results, which show the reliability of the method. Similar results have been frequently obtained, and justify the employment of this method of assay until we can devise a better one.

TABLE.

Determination of the strength of three samples of adrenalin of unknown strength by comparing with a solution of known strength:

| Standard. | Actual strength.<br>100 per cent. | Reported Strength.<br>Standard. |
|-----------|-----------------------------------|---------------------------------|
| A .....   | 85 "                              | 88 per cent.                    |
| B .....   | 40 "                              | 40 "                            |
| C .....   | 130 "                             | 135 "                           |

Adrenalin in crystalline form seems to be, as would be expected, a very stable product. On the other hand, experiments to determine the relative activity of different preparations of the suprarenal gland show quite conclusively that the liquid and powdered preparations, manufactured by the same firm, if not assayed, differ very markedly in their influence on blood pressure. In general, I have found that the fresher the product the greater the uniformity in the activity.

## THE BLOOD-PRESSURE RAISING PRINCIPLE OF THE SUPRARENAL GLAND.\*

JOKICHI TAKAMINE, M.D.

NEW YORK CITY.

Over forty-five years ago Addison directed attention to the relation between a disease bearing his name and certain changes in suprarenal glands. Since then many able investigators studied the nature of this interesting organ and have established beyond doubt that the suprarenal glands possess a marvelous therapeutic value.

The principal investigators in the line of the use of the therapeutic properties of the glands are Brown-Séquard, Oliver, Schafer, Pellacani, Foa, Vincent, Cybulski, Bates, Moore, Swain, Solis-Cohen, Mayer, Reichert and others.

Since the therapeutic value became known many attempts to isolate the active principle of the glands have been made by several physiological chemists. Among these we may mention Prof. J. J. Abel of Johns Hopkins Hospital, Dr. B. Moore of London University and Dr. O. v. Furth of Strassburg.

Professor Abel published the result of his investigation first in 1897. Subsequently, two or three papers on the same subject were published, wherein he announced and claimed that he had isolated the active principle of the gland in the form of its bisulphate and other salts, and named such active principle "epinephrin."

Shortly afterwards O. v. Furth reported the result of his investigation on the gland and criticised Abel's epinephrin, declaring that it is not the pure active principle, but inactive foreign matter contaminated with some of the active principle. Furth claimed the isolation by different methods in the form of iron compound and called his product "suprarenin."

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. Thomas Hunt Stucky, Leon L. Solomon and N. S. Davis, Jr.

Abel obtained his epinephrin by treating in an autoclave benzoyl compound obtained from the gland extract with benzoyl chlorid and sodium hydroxid after the Baumann-Schotten method; while Furth obtained suprarenin from the filtrate in which Abel considered his epinephrin did not exist.

The dispute between these two authors was not altogether amicably solved, for neither of them did obtain their product in sufficiently pure form.

Since last summer I have devoted my attention to this interesting subject and am pleased to announce that I have succeeded in isolating the active principle of the gland in a stable, pure, crystalline basic form.

While I do not desire by any means to usurp the credit due to the pioneer investigators, yet in view of the fact that neither of the authors quoted above have obtained the active principle in pure form and that there still exists some room for controversy between them, I have termed the active principle of the gland as I have isolated it, "adrenalin."

Adrenalin is a light, white, micro-crystalline substance. I have observed thus for five different forms of crystals varying according to the condition of the solution from which they were crystallized, and they are prism shape, fine needles, rhombic plates, boat or leaf shape, and wartlike shape.

Adrenalin has a slightly bitter taste and leaves a numb feeling on the tongue where it has been applied. In dry form it is perfectly stable. Adrenalin shows a slightly alkaline reaction on moistened litmus paper; phenolphthalein also indicates slight alkalinity. It is with difficulty soluble in cold water and more readily in hot water. From the hot saturated aqueous solution the crystals separate on cooling. The colorless aqueous solution of adrenalin is prone for oxidation. It absorbs oxygen from the air, changing its color from pink to red, and eventually to brown.

Adrenalin is easily soluble in acids, forming various salts. It is also soluble in alkalies, but not in ammonia or a solution of alkaline carbonate.

The following are some of the characteristic reactions: The addition of ferric chlorid to a solution of adrenalin or adrenalin salts produces a beautiful emerald green, which by careful addition of caustic alkali, becomes purple and then carmin red. It produces pink coloration with iodine and also with ammonia. It reduces silver and gold salts very energetically, and it produces a beautiful coloration at the proper strength of the solution. Oxidizing agents such as bichromates and ferricyanides behave in a similar manner.

None of the following alkaloidal reagents produces precipitation: Mercurio-potassium iodid, picric acid, tannic acid, phospho-molybdic acid, phospho-tungstic acid, mercuric chlorid, potassium bichromate and platinum chlorid.

The mode of preparing the active principle of the suprarenal glands is as follows: Suprarenal capsules finely disintegrated by suitable means are steeped in water for a period of about five hours at the temperature varying from 50 to 80 degrees centigrade, with frequent agitation and with the addition of water as it evaporates. The temperature of the mass is now raised from 90 to 95 degrees centigrade for the period of one hour, so as to coagulate as much albuminoid bodies as possible.

As the active principle of the glands are prone to absorb the oxygen from the air, to form inactive substance, it is necessary to avoid the exposure of the liquid to the air as much as possible. A layer of fat floating

on the surface of the mass acts very conveniently for this purpose and at the same time it has an effect of retarding evaporation of water as well. The other method of preventing oxidation may be employed at this stage, such as carrying the steeping process in the atmosphere of carbonic acid gas. The mass is now pressed and separated from the liquid portion which contains the active principle. The residual mass is again steeped for hours in warm water, slightly acidulated with acetic or hydrochloric acid, in order to extract the residual amount of active principle. The liquid separated from the mass is now added to the first extract and allowed to separate from the oil. The clear extract is now evaporated in a vacuum pan to a suitable strength. To this concentrated solution about two to three times its own volume of strong alcohol is added, which will precipitate both inert organic and inorganic substances. The inert substances thus separated are washed with alcohol, so as to free them from the active principle. The alcohol solution is now evaporated preferably in vacuum still, whereby the alcohol used is duly recovered. To the residual liquid, ammonia is now added until the solution gets distinctly alkaline and left over for several hours. Yellowish precipitate will be formed, which is the crude adrenalin in a basic form. The precipitate is now filtered, washed with water and dried. The adrenalin usually precipitates in a light yellowish tomato-shape form, which is an agglomeration of the needle crystals under magnifying power, and is more or less contaminated with some coloring matters and some inorganic substance, chiefly phosphates.

Instead of using ammonia, sodium hydrate may be used as a precipitant, but care must be taken not to use in excess, which redissolves adrenalin. The caustic alkali may be used with advantage in the conjunction with ammonium chlorid, or caustic alkali may be used, and afterwards carbonic gas may be passed to remove the excess of caustic alkalies. In fact, the various modifications and combinations of these processes may be adopted.

In order to further purify the adrenalin, the crude adrenalin is dissolved in acid and alcohol and ether are added to a sufficient quantity. A brown-colored precipitate is produced, which chiefly consists of coloring matter and inorganic impurities. The precipitate is separated both by decantation and filtration. The filtrate is now treated by one of the above-mentioned processes, when white crystalline precipitate of adrenalin will be obtained. It is quickly filtered, washed with water and then with alcohol and dried. The process of purification may be repeated if desired.

The physiological activity of adrenalin thus isolated is astoundingly strong. A fraction of one drop of aqueous solution of adrenalin or its salt in strength of 1 to 50,000 blanches the normal conjunctiva within one minute. It is the strongest hemostatic agent known.

The intravenous injection of adrenalin produces a powerful action upon the muscular system in general, but especially upon the muscular wall of the blood vessels and the muscular walls of the heart, resulting in an enormous rise of blood pressure. The accompanying diagram shows the result of three intravenous injections of 1 c.c. of the solution of adrenalin chlorid of 1 to 100,000 into a dog weighing 8 kilograms. It raised the blood pressure corresponding to 30 millimeters of mercury.

The above result, as well as other experiments, indicate that adrenalin is over one thousand times stronger than the fresh glands.

The therapeutic applications of adrenalin are already numerous and new uses for it are constantly found out by investigators. Generally speaking, adrenalin when locally applied is the most powerful astringent and hemostatic known. It is useful in all forms of inflammation and is the strongest stimulant of the heart. It is non-irritating, non-poisonous, non-cumulative and without injurious properties. It has been used with good results in morphin and opium poisoning, in circulatory failure, in the prevention of collapse in anesthesia, and in allied conditions. It is invaluable in carrying out bloodless operations in nose, eye, ear and throat works. It has also given good results in some cases of deafness, hay fever, nasal hemorrhage and various forms of heart disease. Such authorities as Drs. Mayer, Wilson, Bates, Reichert, Ingals, Stucky, Johnson, Chambers, Curtis, Swain and many others have reported very favorable results.

A convenient form to use the adrenalin is in solution of its chlorid one part of adrenalin in one thousand parts of water. It was found desirable to add sodium chlorid to form normal salt solution. In order to insure the stability of the solution, one-half per cent. of chloroform-acetone or chloretone is added with advantage.

Adrenalin can be made in the form of tablets, usually tartrate. The tablet may be made with sodium chlorid and chloretone, so that when it is dissolved in a known quantity of water it forms a solution of desired strength.

The therapeutic efficacy of adrenalin has already been established beyond doubt, and it will unquestionably obtain a prominent place in the materia medica.

In concluding this paper, I desire to state that my thanks are due to Dr. E. M. Houghton, of Detroit, for making the physiological test, and also my thanks and large share of credit are due to Mr. Wooyenaka, my associate, for his energetic and able assistance in accomplishing this interesting investigation.

## NEGLECTED, BUT VALUABLE THERAPEUTIC MEASURES.\*

GEORGE F. BUTLER, M.D.

Professor of Materia Medica and Therapeutics College of Physicians and Surgeons, Chicago, and Medical Superintendent, Alma Sanitarium, Alma, Mich.

ALMA, MICH.

In medicine the law of action and reaction is peculiarly evident in therapeutics. Remedies arise, are boomed and disappear. Some markedly efficient are flung into the background, not because of lack of value, but because of popular prejudice arising in the minds of neuropaths and for commercial reasons affecting physicians. The influence of sects in medicine in this particular is much less than is usually assumed. Sects based on opposition to any therapeutic procedure are expressions of the opinion of neuropaths rather than their cause. Such sects notoriously long retain primitive therapeutic procedures which the profession has outgrown.

Hahnemannism retains the skatologic procedures which the profession long ago rejected with disgust. Thus a Boston homeopathic firm issues a price-list of so-called animal remedies. This offers for sale at a fixed price, on page 20, potentized pediculi pubis, pediculi capitis and pediculi corporis. "Culture" would seem

to have something to do with the last mentioned, for their Bostonian origin is especially dwelt upon. Page 1 offers the "acarus scabies" or "lice insect;" page 15 offers "lachryma filiae" or "tears from a young girl in great suffering;" "carbunculus of the neck very severe" is tendered as a remedy on page 6, and page 7, in addition to the lice insect, offers adenia from the glands in Hodgkin's disease, the ailanthus "bug" and "albuminuria" or "renal albumin." "Fel gryllus Americana" or "Brazilian cricket" is offered on page 11 as a remedy for "suppression of urine." Page 2 offers "anthracin" or pus from an anthra. Page 4 offers "buboin" or pus from "syphilitic bubo." Page 5 offers "calcarea or stone of the kidney, bladder and lungs." Intestinal bladder and nose catarrh are offered on page 6. Page 7 offers a preparation of "chance of syphilis." Page 8 offers "colostrum;" page 9, "crotalin" from the rattlesnake, as well as "diabetes mellitus" and "dropsy-semen." Cancer of the uterus, bowel, face and breast are also offered; as is also "hippозinine" from glands, "lyssin" from hydrophobia, "osteonecrosis" pus from rectal abscess, from "caries of heel" and from septic abscess. "Electricitas" or electricity; "galvanismus" or galvanism; rubrum, flava and ceruli irides, or the red, yellow and blue rays of the spectrum, as well as "Luna" or moonshine, are also tendered as therapeutic aids to the enthusiastic Hahnemannian.

Together with these fetichistic absurdities, Hahnemannism long retained the general therapeutic procedures of the period in which it was born. Although Hahnemann claimed that the homeopathist dispensed with the necessity of employing the barbarous practice of blood-letting<sup>1</sup>, he asserted that beginners and learners may be pardoned for using depleting processes; but if they dare to pride themselves on their pretended improvements and promulgate blood-letting and cupping as processes that are eminently homeopathic, then they make themselves ridiculous, and they ought to be pitied for their dabbling and for their bungling blindness which inflict suffering on their patients. It is laziness or a foolish predilection for the pernicious routine of allopathy, which prevents them from making themselves acquainted with the true homeopathic remedy.

This is the old story of the modern "go-as-you-please" homeopathist, who uses pellets in conjunction with ordinary medicine, but refers the cure to the pellets. The New York homeopathists adopted this system. Dr. Gray, one of the leaders, remarks<sup>2</sup>: "Blood-letting I have not ceased to employ during the eighteen years of my acquaintance with homeopathy. At first, by advice of my learned and lamented predecessor, Dr. Gram, it was continued on purely empirical grounds, but now, and for many years past, I apply it upon the homeopathic basis, having acquired, partly by experiment, partly by reading allopathic authorities to that end, a tolerable pathogenesis of it."

The disuse of blood-letting was simply a consequence of the pandering to popular prejudices for commercial reasons. The persons who had abused venesection joined loudest in the outcry against it. Despite prejudice, based on the fetichistic notion that the life is the blood and allied cant of the followers of Hahnemann and Thompson, blood-letting has held its own, in certain departments of medicine; with the growing knowledge of biochemistry, especially as involved in the blood serum, it is again beginning to assume its old place in

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. Thomas Hunt Stucky, Leon L. Solomon and N. S. Davis, Jr.

1. Chronic Disease, vol. vi, p. 177.

2. Homeopathic Examiner, vol. iv, 1845.

therapy. The former claim that blood-letting would quickest remove toxic products from the body, which could then be replaced with watery solutions similar to blood serum, is now strongly corroborated by the results obtained through the use of the normal salt solution.

Through the influence of the surgical operation *per se*, it was very emphatically pointed out some years ago by J. Williams White, Philadelphia, that but little use of this knowledge has been made. The principal use which emphasizes study of its limitations and indications has been the improvement of peritoneal tuberculosis under simple abdominal section. The rationale of this improvement is readily grasped when the fact is remembered that leucocytes are drawn toward the peritoneum by such an operation, and this would have a profound influence on the general circulation. In consequence of this, too, the leucocytes would be peculiarly stimulated toward phagocytic action in the peritoneum.

For a long time alienists have observed that traumatism exercises a beneficial influence (too frequently but brief in duration, but none the less patent) on chronic forms of insanity. Demented who have accidentally fractured a limb have been noted to improve during the period of recovery and for some time thereafter, when relapse usually takes place. In acute types recovery under these conditions is often permanent. It has also been noted that in families where idiots abound, skull fracture in infancy has led to the disappearance of the idiocy in the victim of the fracture, who, not only becomes sane, but may manifest a high order of intellect. The Australian novelist, Clarke, when a child, had a skull fracture. This was also the case with Vico, Gratre, Fusinieri, Clement VI, Malebranche and Cornelius. To skull fracture in the last three was due, as Lombroso has shown, their genius. I cite the facts simply to show that in the much neglected therapeutic procedure of counter-irritations there are therapeutic possibilities far from being realized. These procedures have fallen into disuse not because of their lack of value, but because of a popular desire for cosmetic therapy.

In no small degree, also, has this desire led to the separation of balneotherapy and hydrotherapy from pharmacotherapy. On principles whose validity is thoroughly recognized, infusions were at one time largely given in connection and coincident with baths. Clinical observation leaves no doubt that this conjunction of therapeutic measures had decidedly beneficial effects. The use of water as an alternative is now more generally recognized than at any other time, yet its employment as an adjuvant because of its alterative qualities, was never more neglected than at present. At the beginning of the century, as the American Dispensary shows, the Brandt treatment of typhoid by balneotherapy was successfully used in the United States. From a survival of the Brandt treatment came the Kibbee treatment of yellow fever, which gave undeniably good results in the late seventies.

These early observers recognized not only the influence of balneotherapy and hydrotherapy *per se*, but the influence of these in extending and increasing the field and effect of pharmacotherapy. Homeopathy, distorting the essential element of the therapeutic procedure, caused its disuse. The dilution absurdity of high potency homeopathy destroyed faith in it among the scientists, at the same time creating prejudice against the correct application of the principle among laymen. The value of the principle, however, was fully sustained by the results obtained at mineral springs, but these were ascribed to the chemical constituents of the water. While, as in

the case of the Hot Springs in the treatment of syphilis, evil has been wrought, it has been wrought by the reliance on the balneotherapy alone, to the neglect of other therapeutic agents as co-adjuvants. The value of these procedures when conjoined has been fully demonstrated by their use in auto-toxemias with neurasthenic elements, whether complicated by the drug habit or not. Here the use of the drip sheet, of the cold pack, of cold sponging, of the greatly diluted medicinal agent, entailing free use of water, have been fully demonstrated to be of great value. The older surgeons, before the days of anesthesia, relieved the patient's system from strain and prepared it to stand the shock of operations by these conjoined procedures. Bleeding was usually added for this purpose. Nerve strain and worry mean increased toxic products to be eliminated, and mean at the same time deficient powers of elimination. Both these conditions indicate, therefore, free uses of water, and also, that watery solutions of medicinal agents are to be employed here.

The use of compound prescription, too frequently confounded with its exact object, the shotgun has lessened since the absurdities of this last were pointed out, and since homeopathy has made the single remedy a popular shibboleth. To some extent this principle is observed in anesthesia and also in certain uses of atropin and morphin. As I pointed out some years ago, this principle could be further extended. Many prescriptions of the older clinicians contained remedies so carefully combined as to emphasize certain common properties and destroy properties antagonistic to them. These were unjustly confused with the shotgun, which was simply a blind firing in the dark, in the hope of, by a scattering fire, hitting something. In fecal anemia, for example, combinations of iron and the salines have been found to act well in conjunction with the vegetable bitters, despite the fact that these are ordinarily given to counteract each other. Sir Andrew Clarke had a favorite mixture for this purpose of the following composition: Iron sulphate, gr. xxiv; magnesia sulphate, dr. vii; aromatic sulphuric acid, dr. vi; tincture of ginger, dr. ii, and infusion of quassia, dr. xvi.

While this has been criticised as a shotgun procedure, it was, for reasons already cited, in connection with hydrotherapy, fully adapted to secure free elimination and the extended action of medicinal agents. It also met the objections to the inorganic iron compounds; another factor in its favor was the failure to arouse mental antagonism to the remedy. This antagonism is more frequently awakened by the palatability of a remedy than by its reverse, and, as states of worry increase auto-toxemia, a remedy which arouses this mental antagonism creates worry and increases auto-toxemia.

The combination just cited from Sir Andrew Clarke is one of a type in which remedies are so combined as to produce an alterative action, which increases metabolism, thereby enhancing the assimilation and benefit of a restorative agent. The physiologic conditions implied even in health by assimilation include the necessary element of elimination of toxic products.

The failure to recognize this has been the reason why iron has so often failed completely in anemia. The success of iron, quinin and strychnin when combined have been due to the recognition of this principle. The same is true of the success of the combination of certain heart tonics and alteratives, which have produced an effect where the simple heart tonics by themselves have failed. The fact has been fully demonstrated that disorders of

the heart do not depend so much on organic lesions as upon the lack of compensation. Even angina pectoris produces sclerosis of the coronary arteries so often associated with it and is not, as a rule, produced by this. The products of auto-toxemia, like toxins of the germ diseases, produce sclerosis. This auto-toxemia may be of local origin, due entirely to the failure to eliminate the toxic results of nerve stress.

Arrhythmia, bradycardia and tachycardia are cardiac manifestations dependent, as Dr. G. Jacoby pointed out years ago, on disturbance of cardiac innervation with interdependent auto-toxemia. Arrhythmia is often a pure neurosis, resulting from toxemia. It is very frequently found in auto-toxemias, where there is a condition of sexual erethism which itself depends on auto-toxemia. The same is true of bradycardia and tachycardia. So long as these so continue that repair out-balances waste, the condition is not dependent on more than biochemic conditions, but when waste exceeds repair organic disease often results.

Because of this mixture of auto-toxemia and disturbed cardio-nervous action, two requirements must be met: 1, the elimination of toxic products by alterative, and 2, the control and stimulation of the local cardiac ganglia, as well as of the cardio-respiratory centers in the medulla. This is but one of a hundred combinations which might be met by careful union of medicinal agents indicated by the patho-physiologic state.

A neglected but valuable alterative nervin is copper. The therapeutists of the close of the eighteenth century believed that copper was of peculiar value in nervous diseases, where an alterative was needed as in chlorosis and anemia, and where neither iron nor arsenic was beneficial. The action of copper on the eye structures indicates that this alleged alterative action had a foundation in fact. It is a normal constituent of the blood and its toxicity has been enormously overestimated. All the therapeutists of the English-speaking countries agree as to its value as an alterative nervin. It has been found of value in all adynamic states by the French therapeutists. Among the combinations peculiarly useful are copper arsenite and copper phosphate.

Massage has undergone the usual variations of trite and useful procedures. The tendency to fashion and fads in therapy, arising from the advertising desire of fashionable physicians, has led more than once during the last two centuries to the disuse and abuse of massage, and has opened a way for the old bone-setters, who are now called osteopaths. Two decades ago they were denominated in Illinois snapping doctors. Massage has also lost caste through the erotic results of misapplication. During the last two decades of the nineteenth century massage shops, as they were called, abounded in all great cities; they received extensive advertisement in quasi reputable newspapers and created a serious prejudice against massage, of which prejudice the osteopaths have largely availed themselves. The old action of massage, as a stimulant to exercise and tissue change, however, has received constant proof sufficient to remove all prejudices against massage in the mind of the scientific therapeutist. In most of the morbid states where exercise is needed, the initial volition of the resolve to take exercise is so fatiguing that all the good effects of the subsequent exercise are nullified. Here massage peculiarly fits the case, and starts the patient on the road to recovery through the physiologic rest it gives by local physiologic exercise and fatigue, without undue strain on a weak will-balance. The Swedish movement

cure is, however, contra-indicated in these cases by its mental effect on the patient, as well as its tendency to produce exhaustion. Both Swedish movement and massage in the hands of a masseur who believes in their occult origin are very dangerous, since mental suggestion of a hypnotic type is apt to affect the patient unfavorably. The most material explanation of their physiologic action should be given their patient, before they are employed, in order to avoid this untoward effect. The addition of massage and Swedish movement to the other measures employed in *tabes dorsalis* has peculiarly beneficial results, both from a physical and mental standpoint, since the patient learns thereby the amount of strength and motor power that he retains despite its seeming loss. Massage in sexual neurasthenic cases, while beneficial, should be carefully watched, since in this class of subjects, whether male or female, pervert tendencies are easily initiated. In all forms of chlorosis and anemia, a sluggish metabolism may be stimulated by massage as well as establishing the initial improvement in auto-intoxication. It should be remembered that in these last states, from neurotrophic causes the skin readily bruises, but such bruises from massage are of short duration, and rapidly disappear under the improvement effected by the procedure.

## TUBERCULOSIS IN STATE INSTITUTIONS.\*

H. M. BRACKEN, M.D.

Secretary Minnesota State Board of Health; Professor of Materia Medica and Therapeutics, University of Minnesota.

MINNEAPOLIS, MINN.

It will be impossible for me to give statistics bearing upon this disease, or to discuss the different methods in vogue in the various states in dealing with it. Such a course is not necessary however. It should be our purpose at the present time to discuss what seem to us the most approved methods, leaving the question as to what is actually done for consideration later. The institutions under the control of the state which demand our attention are schools, hospitals, reformatories and prisons, although we might well go further and discuss conditions in factories, workshops, stores, tenement-houses, etc.

### EDUCATIONAL INSTITUTIONS.

Of schools there are the following: Those for children, either public or private or parochial; and the academies and colleges. Every one will concede, I presume, that tuberculous children should be excluded from the public or parochial schools for at least two reasons: 1, in order to prevent the infection of other children, for in these places the dangers of spreading infection by means of non-disinfected sputum through the use of common drinking cups, text-books, etc., is great; 2, for the good of the tuberculous child itself, for it is not good that these should be housed and cared for in the same manner as are the healthy children.

Tuberculous children should have fewer hours of study. They should have well-regulated physical exercise; especial precautions should be taken to protect them from inclement weather, wet clothing or other conditions tending to irritate the respiratory tract. Undoubtedly some one will say that these children should not be in school at all. It is hardly advisable to take such an extreme position, for many tuberculous children will, if properly cared for, overcome the disease

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Hygiene and Sanitary Science, and approved for publication by the Executive Committee.

and become useful, educated citizens. On the other hand, if excluded from school entirely, they might grow into adult life, lacking many of the qualities of good citizens. This should not be sought after. Tuberculous school children should have among their teachers, one giving entire attention to their physical training. Weeding out from our public schools the children that are tuberculous is one of the most important functions of medical inspectors. It may not be necessary to exclude all tuberculous children from private schools, academies, colleges and universities, but all of these institutions should have thorough medical inspection, and, in connection with such, there should be definite methods of living laid down for those that are affected. The student suffering from this disease should never be allowed to room with or sleep with the non-tuberculous. It is not long since my attention was drawn to a sad case. Two university students roomed and slept together. At the outset one was tuberculous; the other was not. Neither of these young men were familiar with the nature of the tubercular infection. Probably at the outset the tuberculous individual did not even know that he had this disease. Later, the affected student died of the disease; not, however, until his roommate had also become infected, following him to the grave within a year. Such an unfortunate occurrence should not have been possible in an institution for advanced study. The physical condition of this infected student should have been known. He should have been required to live in such a way as not to have endangered others. His advanced education, if permitted at all, should have been directed by a competent physician, and he should not have had a roommate.

So far we have been dealing with schools that are in a way free from state control. There are others for which the state is directly responsible. The state schools for the blind, the deaf and dumb, the epileptics, the dependent and neglected children, reformatories, etc., can and should be thoroughly inspected, and a careful watchfulness should be kept over any of these unfortunates who may show any symptoms of tuberculosis. While it may not be necessary in all cases to isolate such children, they should most certainly have separate sleeping rooms, together with a careful regulation of out-of-door and school life. It is quite possible that many of these children are more prone to tubercular infection than are those under our general public school system.

In the schools for the feeble minded we find quite a different class of people to deal with; a people who are irresponsible and incapable; a people whom it is difficult to regulate; a people whose habits are often filthy. Strange as it may seem, one of these filthy habits is to a certain extent protective. I refer to the habit of swallowing sputum. If it were not for this habit it would be almost if not quite an impossibility to prevent the general infection of the wards and rooms in these schools. With this habit we should naturally expect to find a large percentage of cases with intestinal tuberculosis and such is the fact. The record of one institution<sup>1</sup> with which I am familiar, is as follows:

| Year | Average Attendance. | Deaths. | Deaths from Tuberculosis. |
|------|---------------------|---------|---------------------------|
| 1881 | 22                  | 2       | 1                         |
| 1882 | 30                  | 2       | 1                         |
| 1883 | 37                  | 1       | 1                         |
| 1884 | 45                  | 4       | 3                         |
| 1885 | 78                  | 7       | 3                         |
| 1886 | 78                  | 9       | 2                         |

1. Furnished me by Dr. Huxley, of the School for Feeble-Minded, at Faribault, Minn.

| Year.                  | Average Attendance. | Deaths. | Deaths from Tuberculosis. |
|------------------------|---------------------|---------|---------------------------|
| 1887                   | 104                 | 6       | 2                         |
| 1888                   | 157                 | 9       | 3                         |
| 1889                   | 198                 | 11      | 3                         |
| 1890                   | 268                 | 12      | 2                         |
| 1891                   | 301                 | 18      | 4                         |
| 1892                   | 305                 | 15      | 5                         |
| 1893                   | 352                 | 13      | 6                         |
| 1894                   | 456                 | 24      | 6                         |
| 1895                   | 440                 | 22      | 4                         |
| 1896                   | 435                 | 18      | 4                         |
| 1897                   | 511                 | 26      | 3                         |
| 1898                   | 590                 | 39      | 10                        |
| 1899                   | 630                 | 24      | 6                         |
| 1900                   | 668                 | 30      | 11                        |
| 1901 (Jan. 1 to May 5) | 758                 | 9       | 3                         |
| Total                  | 301                 | 79      |                           |

The average attendance is for the fiscal year, July 31-July 31. The deaths are for the calendar year.

W. Huxley further states, that after a careful study of the records in regard to tuberculosis at the time of admission, I believe that the year beginning April, 1900, may be taken as a fair example. There were 107 admissions. Tubercular: positive, 8; probable, 5; questionable, 6. The positive covers those cases sufficiently advanced to warrant the statement.

Under probable are included those cases in which the findings lead to a strong suspicion of tuberculosis, but which are not sufficient to justify a positive statement of the condition.

Questionable cases comprise those where the condition of the patient, shape of the chest, expansion, etc., would lead one to be on his guard as to a favorable prognosis, but where unfavorable conditions render it impossible to demonstrate the disease clinically.

Below is a list of autopsies, performed this fiscal year:

| Case.      | Age, yrs. | Sex. | Tuberculosis of lung. | Tuberculosis of intestine. | Diagnosis—clinical.        |
|------------|-----------|------|-----------------------|----------------------------|----------------------------|
| A. . . . . | 4         | F    | Yes.                  | Yes.                       | Chronic enteritis.         |
| B. . . . . | 28        | M    | Yes.                  | Yes.                       | Tuberculosis—general.      |
| C. . . . . | 7         | M    | No.                   | No.                        | Nephritis.                 |
| D. . . . . | 9         | F    | Yes.                  | No.                        | Tuberculosis—lung.         |
| E. . . . . | 8         | M    | No.                   | No.                        | Gastro-enteritis.          |
| F. . . . . | 34        | M    | Yes.                  | Yes.                       | Tuberculosis—general.      |
| G. . . . . | 50        | M    | Slight.               | No.                        | Epilepsy.                  |
| H. . . . . | 10        | M    | No.                   | No.                        | Chronic gastritis.         |
| I. . . . . | 26        | M    | Yes.                  | Yes.                       | Epilepsy and tuberculosis. |
| K. . . . . | 50        | M    | Yes.                  | Yes.                       | Tuberculosis—general.      |
| 10         |           |      | 1                     | 5                          | Three not tubercular.      |

\* Tuberculosis demonstrated clinically about one month before death.

† In this case the patient expectorated freely and was provided with a sputum cup; tubercle bacilli were found in sputum; impossible to get sputum in other cases.

All of above were low-grade cases, except last.

Cases of marked tuberculosis are taken to the hospital, placed in a separate ward, cared for under antiseptic precautions. All outside cases are given the benefit of sunshine and open air as much as possible and those in charge are instructed as to the nature of the disease.

Dr. Rogers states that a few years ago, when the institution was not quite so badly crowded, the attending physician selected the tuberculous cases, or those in whom he suspected tuberculosis, and arranged to have them, under charge of a special attendant, out of doors in all good weather, and pretty well separated from other children when in the house. While this plan was carried out, there were fewer new cases developing in the institution than before.

As this institution is under most careful and efficient management, the record is probably up to, if not above, the average for others of a similar nature. It is noticeable that with this high mortality from tuberculosis among defectives, there is not a single instance of probable infection of attendants.

#### INSTITUTIONS FOR THE INSANE.

Still other conditions relative to the care of the tuberculous in state institutions are presented in the hospitals for the insane; conditions that are somewhat peculiar. It appears that it is not at all uncommon for tuberculosis to be held in abeyance apparently in the insane, and yet these patients in whom the disease exists in non-progressive form are capable of infecting others. We, therefore, find in these hospitals two sets

of tuberculous patients: viz., 1, those who were tuberculous before their admission but in whom the disease is apparently non-progressive; 2, those who have become infected since entrance into the institution and in whom the disease is progressive, later ending fatally. The records of three institutions with which I am somewhat familiar is as follows:

| Year.       | 1           |                           | 2           |                           | 3           |                           |
|-------------|-------------|---------------------------|-------------|---------------------------|-------------|---------------------------|
|             | Population. | Deaths from Tuberculosis. | Population. | Deaths from Tuberculosis. | Population. | Deaths from Tuberculosis. |
| 1890 .....  | .....       | 8                         | 967         | 8                         | 82          | ..                        |
| 1891 .....  | 949         | 10                        | 1054        | 15                        | 122         | ..                        |
| 1892 .....  | 935         | 4                         | 1058        | 11                        | 245         | ..                        |
| 1893 .....  | 599         | 10                        | 1071        | 19                        | 352         | 4                         |
| 1894 .....  | 938         | 8                         | 1115        | 27                        | 532         | 5                         |
| 1895 .....  | 936         | 11                        | 1120        | 18                        | 725         | 5                         |
| 1896 .....  | 997         | 9                         | 1138        | 21                        | 783         | 8                         |

There is a tendency among the insane to swallow sputum, but this tendency is not so general as among the feeble-minded. On the other hand, it is no uncommon thing to find an insane person exceedingly filthy with reference to expectoration. It is no uncommon thing for attendants at asylums to become infected at such institutions and die. It would seem that of all state institutions in which an attempt should be made to control tuberculosis, the hospitals for the insane should take first place, for many of the patients recover in part or entirely from their insanity and are returned to their homes. If such restored patients have been infected with tuberculosis while in the institution, they will in all probability not only die of this disease, but will spread infection to other members of their families.

In a paper which I read before the Conference of State and Provincial Boards of Health at Nashville, in 1897, I presented the following statements and these hold equally good at the present time:

In a paper by Dr. George H. Rohé, upon sanitation in hospitals for the insane, he says: "The greatest scourge of these institutions is tuberculosis, and I fear the apathy with which this disease is regarded by physicians in charge of the insane is largely due to the prevalent belief that there is an etiologic relation between phthisis and insanity. I am convinced, however, that unprejudiced observation will show that the prevalence of tuberculosis in hospitals for the insane is due to the great facilities for infection and the lack of attention to the means of restricting the same. The American Public Health Association has, by the report of its committee on restriction of tuberculosis, pointed out the means of limiting the spread of this disease. By the adoption of these means, the percentage of tuberculous deaths to the general death-rate in one hospital, has been reduced in the course of three years from an average of 25 per cent. to a fraction under nine per cent.

I was interested in this hospital report from Dr. Rohé, at the Maryland Hospital, Catonsville, and wrote to Dr. Wade, his successor, to learn the present condition of the tubercular patients. He informed me that the death-rate from tuberculosis for 1896 was but 6.1 per cent. Dr. Wade described the manner of caring for the tuberculous insane in this hospital as follows:

"The sputa of the suspected case is examined, and if the bacilli are found the patient is placed in a single room, the walls of which are painted and can be easily disinfected. The furniture consists of an iron bedstead which is readily cleaned. There are no curtains at the windows and no carpet on the floor. The patient is persuaded, if possible, to expectorate into a vessel, which is disinfected at proper intervals. If the patient expectorates about the room, no harm can be done, however, as everything can be readily washed with a disinfectant. The bedding is properly cared for, and is used for no other bed. After the death of the patient, the room and all of its contents are thoroughly disinfected."

It may be well to place Dr. Wade's opinion, relating to tuberculosis among the insane, against the older views which I have already given. He states, as reasons for a high mortality from this disease in these hospitals: 1, the fact that the physical condition of the insane patient is very much depleted on admission; 2, the necessary confinement in the building; 3, the difficulty of isolation; 4, the lack of proper care and disinfection; 5, the fact that many of the patients do not complain of their ailments and that the tuberculous process is well established before discovered.

Dr. Tomlinson, Superintendent of the State Hospital for the Insane at St. Peter, Minnesota, believes in the transmutation of insanity and phthisis. At the same time he believes that most of the cases of tuberculosis in these hospitals originate by infection while in the hospital, and that patients having a direct heredity of phthisis are not likely to die from this disease. In proof of this he quotes from the hospital's statistics as follows: "During a period of two and one-half years, out of 695 patients admitted, 70 had a history of phthisis in the family; and 5 were suffering from phthisis when admitted. During this same period, 19 patients died of phthisis, and not one of these had a family history showing that disease."

He believes that the *materies morbi* for tubercular infection is always present in the old-style hospital and that the poor hygienic surroundings due to overcrowding have much to do with its development. This is illustrated by the fact that at times a patient who becomes infected with tuberculosis and is rapidly failing may improve and apparently recover when placed under better sanitary conditions. We should, therefore, have no hesitation whatever in saying that the isolation of the tuberculous insane should be insisted upon, even though such a procedure would require the establishment of a hospital especially for this purpose.

#### PRISONS.

It should be a simple matter to control tuberculosis in prisons, for the individuals are under absolute control. In all modern prisons each prisoner has his own cell. It is a simple matter, therefore, to set aside certain cells in which to confine tuberculous prisoners. These individuals should be given a special diet and should be kept at work in the open air, if possible. They certainly should not be placed at work in shops or factories with other prisoners. Such a system, I am happy to say, is carried out at the Minnesota state prison with most gratifying results, for at present there is not a single prisoner suffering from tuberculosis in confinement at that institution. Dr. B. J. Merri'l, physician in charge, established the system of isolation, special diet, etc., in the summer of 1894. At this time

he set aside a group of cells now known as "tuberculous row;" with the appearance of any suggestive symptoms of tuberculosis a prisoner is carefully examined from time to time and as soon as the presence of tuberculosis is recognized he is placed in one of these cells. This does not mean that he is placed in an infected cell; far from it, for these cells and their contents receive special attention. All bedding and clothing is disinfected and laundered separately. The prisoner is required to expectorate into a spit cup containing a disinfectant, and especial care is given to the cleansing of the cell from day to day. Should a tubercular prisoner die, his clothing and bedding are disinfected or destroyed and his cell is thoroughly cleansed before being placed again in service.

These methods adopted at Stillwater may not be unusual in prisons but it is not universal. In strong contrast with the condition at the Stillwater prison is that which exists at the Indiana State Reformatory at Jeffersonville. This institution is poorly located on low ground, and in spite of protests it is overcrowded to such an extent that bunks made of rough boards fill up all the available space on the floors of the cell room and many cells are made to accommodate two instead of one man. Buildings that were planned to accommodate 536 prisoners have now an average population of 900. Of course, it is not possible at this place under existing conditions to isolate tuberculous prisoners.

The records of this institution from Nov. 1, 1896, to Oct. 26, 1900, divided into two periods of two years each, show the following concerning tuberculosis:

*First period.*—Tuberculous inmates under treatment, 52; deaths from tuberculosis, 15. Total deaths, all causes, 23; percentage of deaths from tuberculosis, 65.

*Second period.*—Tuberculous inmates under treatment, 396; deaths from tuberculosis, 23; total deaths, all causes, 32; percentage of deaths from tuberculosis, about 72.

These numbers represent only the cases that have been on the sick list. Undoubtedly there were others who, if they had been examined carefully, would have shown symptoms of the disease. It would seem that this institution, with the assistance of that reaper whom we call death, might be able in the course of a few years to eliminate from Indiana its tuberculous reformatory prisoners.

As race has much to do with the susceptibility to tuberculosis and as negroes and people of mixed negro blood are said to be especially liable to contract this disease, and, as there are many more negroes in the Indiana reformatory than in the Minnesota prison, it may be said that a comparison of these two institutions is unfair. As a matter of fact, the difference in the susceptibility to tuberculosis of the people in these two institutions is not so great as might appear to the casual observer. If, however, it is conceded that climate and individuals favor the Minnesota institution, there is then the more reason for the use of strict sanitary measures at the Indiana reformatory.

**Etiology of Diabetes.**—Erichsen suggests in the *St. Petersb. Week.*, that diabetes may be due to sclerosis of the vertebral and basilar arteries. Patients with diabetes frequently exhibit indications of arteriosclerosis. The vertebral and basilar arteries pass along the medulla oblongata and send ramifications to the floor of the fourth ventricle. He bases treatment of diabetes on this principle, and administers potassium iodid in combination with sodium salicylate, as in case of arthritis and arteriosclerosis in general. The favorable effect may reach the arteries of the medulla and thus ensure better nutrition of the "sugar center" and improve the symptoms of the diabetes.

## PUBLIC SANITARIA.\*

C. P. AMBLER, M.D.

ASHVILLE, N. C.

The large number of alleged "cures" for tuberculosis which are constantly appearing as new remedies in the treatment of this disease only go to prove that the medicinal treatment of tuberculosis, if depended upon empirically, is failing in the object to be attained. We have elsewhere (Columbus meeting of the American Medical Association) claimed that the hygienic treatment of this disease should occupy first place, in no matter what climate or under what conditions the patient was being treated; that climate should occupy second place, while medication in point of preference should be given third place. The consensus of opinion of all writers who deal largely with this disease now practically agree in this, the same proving that the hygienic care of the patient is of the greatest importance.

The question immediately arises as to how we can place our patients under the best hygienic conditions. I understand that under "hygienic conditions," one of the things of greatest importance is the education of the patient in what to do and what not to do. It becomes the duty of the physician to instruct his patients carefully and to see that these instructions are carried out. This is generally a very difficult matter where the patient is engaged in his daily work and is frequently one of the greatest drawbacks where our patient is in the ordinary boarding-house of a health resort. The sanitarium undoubtedly offers the best possible advantages for the proper instruction of a patient, both as regards exercise, diet and the many little things which go to make up the daily round of life.

Unfortunately, a large percentage of the phthisical of this country are so situated that they can not enter a private institution for such treatment on account of the expense involved; this brings us to the point of our paper, i. e., does the state owe a duty to the phthisical poor?

The communicability of this disease makes sanitation a necessity, always. It is foolish for us to create the impression among the laity that the disease is violently contagious; but nevertheless, each case is a menace to those with whom he comes in contact, and particularly among the poor is the death-rate in this disease high. Each state takes care of its insane and spends large sums yearly upon the maintenance of such hospitals. The inmates of these institutions are hopeless as far as future citizenship is concerned, and, while the state recognizes that it can not hope to bring them to a point of usefulness, it has already become the fashion in the different states to take good care of the insane as well as their blind, their deaf and dumb, their epileptic and their criminals (and who shall say that the latter are not simply persons of diseased minds?). If the state acknowledges the duty of caring for all these, it should certainly recognize the same duty toward this large class of patients who become diseased through no fault of their own, particularly as in the case of the phthisical, where each and every patient is a menace to those with whom he comes in contact, and in many cases becomes a charge upon the community in which he resides. He is a danger to his friends, he is a danger, to a certain extent, to the community at large, and, as the state now sees fit to enforce laws and regulations in most

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Hygiene and Sanitary Science, and approved for publication by the Executive Committee.

other contagious diseases, the time is shortly coming when the same action will be taken in regard to tuberculosis; particularly is this shown to be true when we investigate statistics and find that about one-tenth of all the deaths in this country is due to this disease.

The poor man who develops tuberculosis, as a rule, dies of the same, dies in distress, dies suffering for the need of the simplest comforts and attentions, and dies only after he has infected the whole community in which he lives. If tuberculosis was as rare to-day as leprosy and if the ravages of this disease could be seen upon the skin as in that trouble, we would to-day be isolating our tuberculous patients in pest-houses and enforcing them away from their friends and their families. It is the insidiousness of the disease, together with the fact that it involves organs and tissues which are not discernible to the eye, that makes people at large so indifferent to the malady as they are. Because they can not see the disease, they accept the same as a visitation of Divine Providence and seem to have no fear of it, even when for ages back it has been known that the disease is more or less communicable.

The rich can and do take care of their own; but the poor, the needy poor, and those who are only poor on account of the disease, and those, who prior to their affliction, were engaged in daily labor, in many cases working for the state, what shall we do with these? Are they to receive no consideration at the hands of the community in which they have resided and been good citizens?

I believe that all will recognize before many years that the state has a duty toward these poor, both on account of their unfortunate condition and on account of the contagion which they spread. Many of our states are already taking the matter up, but this movement has been altogether too slow.

In 1889 when I first started into the sanitarium treatment of this disease there were only two institutions of the kind in this country, to-day there are over thirty; of these but two are state institutions and one is National (conducted by the Marine and Army corps); the remainder are private institutions, conducted by private individuals, corporations or charitable institutions. Our politicians will soon be compelled to adopt some measures to stop the spread of this disease and such institutions for the care of the phthisical poor will undoubtedly be one of the first measures. These institutions will probably be conducted on the cottage plan and not with large wards or open dormitories. They will be situated at an altitude of between two and three thousand feet; away from towns; with level grounds; groves of trees; good water and drainage, and should be easy of access. The grounds should be large and the inmates allowed and required to assist in the care and cultivation of the same, under the constant supervision of the physician in charge.

Under some such plan as this many of the phthisical poor could be cured and others greatly benefited. The one great curse to the poor man suffering from this disease is the fact that he continues in his labors until his condition is such that no improvement is possible. If the state would give him the care which he deserves he would then be more free and better able to take this care at an earlier period and with better prospects of recovery.

I firmly believe that each state should levy sufficient taxes for their consumptive poor and that each county should pay these taxes pro rata, according to the number

of phthisical patients in the county requiring assistance. This would force the keep of these people upon the county in which they had developed their trouble and would necessarily sooner or later result in better hygienic laws in that county. It would also remove to a distance many virulent sources of infection and give the county better chances of recovering from the disease.

Some will say that the segregation of tuberculous patients will only result in more virulent local infections of certain districts; this is nonsense, as it can be clearly proved to-day that those institutions which have been conducted in this country have, in the rarest exceptions, had the disease develop on their grounds.

If the state is to take hold of the subject, it will only do so upon the solicitation of the profession, and if the profession who now recognize the necessity of some such legislation do not openly advocate the same and educate the people up to the point where they recognize the necessity of such legislation, then we are failing in our duty to the phthisical poor and to the community at large.

We, as physicians, should also attempt to educate those who so generously endow hospitals, to the necessity of establishing institutions for the treatment of this disease for the needy and deserving poor. When we look over the large number of hospitals in some of the large cities and see how many of these are sufficiently endowed to guarantee their permanent finances, and when we look further and see how few of these have either special wards or special means for caring for this large class of the unfortunate, we can only censure ourselves that such is the case. The public-spirited citizens who endow these hospitals do not realize the amount of suffering and distress, want and destitution that exists among our poor consumptives, and as before stated, we, as physicians, should undertake to see that these people have a better understanding of these necessities. If we do there can be no doubt whatever but almost every city in the country would have an institution either in the suburbs or in the country for the care of the tuberculous poor of the city in question.

Let us appeal not only to the state, but let us appeal to those who are rich also and who could certainly place their money to no better advantage than thus relieving the suffering and distress of their fellow man. Let us advocate cottages for the curable cases and let us advocate separate cottages for the incurables, and surely if those who have money to apply to a charity cause could once be made acquainted with the great amount of good which could be done, especially among these latter cases, our appeals would not be in vain.

In order to accomplish anything, however, we will have to work; work individually and work together and not each man depend upon the other, but organizing a crusade in this direction, if each physician would make himself a committee of one to see that the same is advocated in the proper place and time, a year or two would undoubtedly produce great and good results.

Let us remember that it is not always necessary to send the consumptive away from home. Good work can be done any place in the country if the proper hygienic measures are carried out. And especially let us advocate the placing of the deserving and needy incurables in institutions removed from the centers of population.

In order to be able to place before you what has already been accomplished by the different states in

this country, I have addressed circular letters to the secretaries of the different State Boards of Health asking them certain questions, which we give below, together with the replies received and the names of the secretaries of the State Boards of Health answering.

Summarizing the reports received from the 43 different states answering we find under Question 1.—That in 12 states pulmonary tuberculosis is classed by the state laws as a contagious disease, and in 28 the disease is not mentioned in any way under or in the state laws. In 13 states the state laws do not mention the disease, but the State Boards of Health recognize that the same is a communicable disease and are now endeavoring to get state laws passed.

Question 2.—By the reports received we find that in 21 states there has been direct legislation to prevent the spread of pulmonary tuberculosis and in 22 states there has been no direct legislation to prevent the spread of this disease. Under this head we find the interesting fact that in 11 of those 22 states which do not recognize this disease as a disease in the human being, stringent measures have been passed and are now in active force to prevent the spread of tuberculosis among cattle. The state apparently recognizes a greater duty to the cattle of the state than to the citizens, although the laws passed are supposed to be passed for the benefit of the population. In 10 states the only measures that have thus far been taken by the state have been to distribute literature in an attempt to educate the people as to the dangers and communicability of this disease. The report from Rhode Island shows that \$15,000 is annually given the Board of Health by the state to pay for such cattle as the Board finds tubercular and is destroyed. Under this question our report shows but three states in which local ordinances concerning expectorating in public places have been passed and are enforced.

Question 3.—In but 5 states of the 43 reporting is there any provision made for the care of the poor tubercular patient by the state, namely, New York, Massachusetts, Maryland, Pennsylvania, Ohio (municipal); while Connecticut, Michigan, Maine, Minnesota and Pennsylvania now have pending bills before their legislatures for the establishment of state institutions.

Question 4.—Of the 43 states reporting, 8 states report private institutions for the care of tubercular patients, while the whole number of such institutions reported amounts to 26, the majority of which are situated in Boston and Philadelphia. (Of the whole number reported 8 are simply wards in general hospitals, which wards are set aside for tuberculous patients.) In 4 states the State Board of Health and State Medical Society are now jointly working together for the establishment of such institutions for the care of the indigent poor.

Question 5.—Of the whole number of 43 states reporting, in only 18 instances was the state able to furnish statistics as regards the prevalence of tuberculosis in the state. In 17 instances the State Board of Health records were sent, but from many of these it was impossible to obtain figures or data which would enable one to arrive at anything like definite conclusions. By averaging the total number of deaths from all causes from all the states reporting, it appears that about one death in every ten is from some form of tuberculosis, whereas, the same inquiry made six years ago showed that one death in each six of the total deaths was due to this same disease.

In 27 of the 43 states reporting, it was admitted by

the reporter that the state records were in bad shape, thus further showing that the state pays little attention to this, one of the communicable and most fatal diseases. The most progressive states, judging from the reports sent and from the work already done in the states, are (in proportion to the amount of work done) Maine, Massachusetts, Pennsylvania, New York, Michigan, Rhode Island and Vermont.

Judging from the summary of the whole report received from these states a systematic effort is now being made to educate the people of the various states as to the danger and contagiousness of pulmonary tuberculosis, and in most of the states the state now recognizes the disease as a disease in cattle, but absolutely ignores the same in the human being. Many of these states seek to prohibit the spread of the disease in the human being (without so mentioning the fact) by slaughtering the cattle that are found to be tubercular. It further appears that many municipalities compel the inspection of cattle slaughtered to prevent the consumption of meat from tuberculous cattle, but these same municipal authorities fail to recognize or admit that such a disease already exists among the people of their municipality.

It would appear as though in most of the states we are attempting to clean and purify our homes by sweeping the front steps; in other words, we seem content to live with, eat with, sleep with, and come in constant contact with the filth of the disease of tuberculous patients when occurring in our homes and cities, and that our sense of duty only urges us to make strenuous efforts toward purifying the cattle herds of the country.

Of the whole number of states reporting, in but one instance is there no provision made for the care of the insane and in but two instances no provision for the blind, and I believe that almost every county of every state reporting has some provision for the care of the destitute poor. In most of these states we find pest-houses where are confined those persons having acutely contagious diseases, and throughout the breadth and length of the land we find that the endowment of hospitals for the epileptic, the blind, the insane, the crippled, the deaf and dumb, the aged, the poor and, in fact, the diseased in either mind or body, from no matter whatever cause (other than tuberculosis) are constantly being endowed by private individuals, established by the states, established by the counties and municipalities, but that this great plague which annually kills one out of every ten persons dying in our country, has received practically but little attention or recognition on the part of the state or the philanthropist.

#### REPORT.

Question No. 1—"Is pulmonary tuberculosis classed as a contagious disease under your state laws?"

Question No. 2—"Have any laws or steps been taken by your state to prevent the spread of pulmonary tuberculosis?"

Question No. 3—"Are there any institutions conducted by your state for the cure or treatment of pulmonary tuberculosis?"

Question No. 4—"Do you know of any private institutions in your state conducted for the cure or treatment of pulmonary tuberculosis? If so, where located?"

Question No. 5—"Can you furnish me anything in the way of statistics, showing the prevalence of pulmonary tuberculosis in your state?"

Massachusetts—Samuel W. Abbott, Sec. State B. O. H. Question 1—No. Question left to discretion of local board of health. Question 2—No direct legislation. State B. O. H. has applied for such and same now pending. Question 3—Rutland Hospital for Consumptives, 200 beds. Question 4—Cullis Home, Boston, 44 beds; Free Home for Consumptives, Boston; Chamming Home for Consumptive Women, 17 beds; Home Good Samaritan, 25 beds; Carney Hospital Wards; Sharon Sanitarium, 20 beds. Question 5—Complete state records.

Pennsylvania—Lawrence Flick, M.D., Sec. State B. O. H. Question 1—Yes. By power conferred upon state B. O. H., which body so classifies the disease. Question 2—No. Indirectly the State Veterinary Department exercises some control. Question 3—No. State appropriates \$5000 annually to Rush Hospital for Consumptives, and will likely appropriate money to State Hospital this year. Question 4—Hosp. Dis. of Lungs, Women, Phila., 40 beds; Hosp. Dis. of Lungs, Men, Phila., 10 beds; Rush Hospital of Phila., 30 beds; Nott Home of Jewish Hosp., 20 beds; Free Hosp. Poor Consumptives, 35 beds; Consumptive Wards in the Episcopal, Samaritan, German, University and other hospitals. Question 5—There are probably 100,000 cases of pulmonary tuberculosis in Pennsylvania at present. 6000 consumptives die in Pennsylvania every year. Complete state records kept.

North Carolina—R. H. Lewis, M.D., Sec. State B. O. H. Question 1—No, not specifically. Question 2—Distribution of literature; local expectoration ordinance; local notification ordinances. Question 3—No. Question 4—Winah Sanitarium; Pigbone Sanitarium for Colored Consumptives; St. Joseph's Retreat. Question 5—Complete B. O. H. reports.

Colorado—G. E. Tyler, Sec. State B. O. H. Question 1—No. Question 2—Educational only; 17,000 circulars mailed during past year. Question 3—No. Question 4—Oakes Home, Denver. Question 5—Complete B. O. H. reports.

Maryland—John S. Fulton, Sec. State B. O. H. Question 1—No, but mentioned in regulations for transporting dead bodies. Question 2—No, except as pertains to cattle and dairies. Question 3—Hospital for Consumptives at Towson. Question 4—No. Question 5—No.

Connecticut—C. A. Lindsey, Sec. State B. O. H. Question 1—No, except as applies to cattle. Question 2—No, only as regards cattle. Question 3—Bill now pending, asking for \$150,000. Question 4—No. Question 5—Complete B. O. H. reports.

Mississippi—J. F. Hunter, M.D., Sec. State B. O. H. Question 1—No, but B. O. H. so considers it. Question 2—No. Question 3—No. Question 4—No. Question 5—No.

Kentucky—J. N. McCormick, M.D., Sec. State B. O. H. Question 1—Yes. Question 2—Only advisory, and distribution of literature. Question 3—No. Question 4—No. Question 5—No.

Virginia—Paulus A. Irving, M.D., Sec. State B. O. H. Question 1—Yes. Question 2—Distribution of literature only. Question 3—No. Question 4—No. Question 5—No. No reliable data.

Louisiana—G. T. Patton, M.D., Sec. State B. O. H. Question 1—No. Question 2—No. Question 3—No. Question 4—Tolson San., at Covington. State B. O. H. now trying to establish a state institution. Question 5—No.

Arkansas—R. B. Christian, M.D., Sec. State B. O. H. Question 1—No. Question 2—No. Question 3—No. Question 4—No. Question 5—No.

Michigan—H. B. Baker, M.D., Sec. State B. O. H. Question 1—Yes. Question 2—Distribution of literature and notification by physician. Question 3—No, but two bills now pending. Outlook not good. Question 4—No. Question 5—Complete State B. O. H. reports.

Iowa—J. F. Kennedy, Sec. State B. O. H. Question 1—Yes. Question 2—Distribution of literature only. Question 3—No. Question 4—Dr. J. W. Kime's San. Question 5—No. Nothing reliable.

Wisconsin—V. O. B. Wingate, M.D., Sec. State B. O. H. Question 1—No. Distribution of literature; education of citizens. Question 3—No. Question 4—No. Bill now pending and prospects good. Question 5—Complete State B. O. H. records.

Kansas—W. B. Swan, Sec. State B. O. H. Question 1—No, but state gives local B. O. H. authority to so classify. Question 2—Distribution of literature only. Question 3—No. Question 4—No. Question 5—1898 total deaths, 5288, of which 480 were from tuberculosis. Complete State B. O. H. records.

Ohio—C. C. Probst, Sec. State B. O. H. Question 1—No. Question 2—Only in educational way. Question 3—No. But one municipal hospital at Cincinnati. Question 4—No. Question 5—Nothing very reliable.

Maine—A. G. Young, Sec. State B. O. H. Question 1—No, but power given local B. O. H. to so classify. Notification compelled. Question 2—Distribution of literature. Question 3—No, "not yet." Question 4—No. Question 5—Complete State B. O. H. records. First state to distribute literature.

Texas—W. F. Blunt, Sec. State B. O. H. Question 1—No. Question 2—No. Question 3—No. Question 4—Dr. L. W. Cock's San., at Boerne. Question 5—No.

North Dakota—H. H. Healey, M.D., Sec. State B. O. H. Question 1—No. Question 2—No. Question 3—No. Question 4—No. Question 5—No. Records, bad shape; disease not prevalent.

Nebraska—B. F. Grummer, M.D., Sec. State B. O. H. Question 1—No. Question 2—No. Question 3—No. Question 4—No. Question 5—No.

South Carolina—James Evans, M.D., Sec. State B. O. H. Question 1—Yes. Question 2—Only as pertaining to transportation dead bodies. Question 3—No. Question 4—No. Question 5—No. Records not complete.

Rhode Island—Gardiner J. Swartz, M.D., Sec. State B. O. H. Question 1—No, except in cattle. Question 2—\$15,000 given B. O. H. annually to pay for tubercular cattle. No other. Question 3—No. Last session took the matter up for investigation. Question 5—Yes. Complete State B. O. H. records; 1 death to every 450 population.

Wyoming—Geo. P. Johnston, Sec. State B. O. H. Question 1—No. Question 2—No. Question 3—No. Question 4—No. Question 5—No. B. O. H. just organized; disease practically unknown.

Washington—D. P. Newman, Sec. State B. O. H. Question 1—Yes. Question 2—Yes. Question 3—No. Question 4—No. Question 5—No.

District of Columbia—W. C. Woodward, M.D., Sec. District B. O. H. Question 1—No. Question 2—No, except expectoration laws and control of milk. Question 3—No. Question 4—No. Question 5—B. O. H. reports.

Minnesota—H. M. Bracken, Sec. State B. O. H. Question 1—No. Question 2—No. Question 3—No, but last legislature took matter up. Question 4—No. Question 5—Statistics incomplete.

Oregon—B. F. Miller, M.D., Sec. State B. O. H. Question 1—No. Question 2—No. Question 3—No. Question 4—No. Question 5—There are none.

Vermont—H. D. Nolten, Sec. State B. O. H. Question 1—No.

but State B. O. H. so considers it. Question 2—No, except as applies to cattle. Question 3—No. Question 4—No. Question 5—9.28 per cent. of all deaths are from tuberculosis.

New Jersey—H. Mitchell, M.D., Sec. State B. O. H. Question 1—Yes. Question 2—Expectoration and notification ordinances by local municipalities. Question 3—No. Question 4—No. Question 5—Complete State B. O. H. reports.

Utah—J. B. Beatty, Sec. State B. O. H. Question 1—No. Question 2—No. Question 3—No. Question 4—No. Question 5—No.

South Dakota—Wm. Edwards, Sec. State B. O. H. Question 1—No. Question 2—No. Question 3—No. Question 4—No. Question 5—No. Disease rarely seen.

Montana—A. F. Longeway, M.D., Sec. State B. O. H. Question 1—No, but B. O. H. so considers the disease. Question 2—No. Question 3—No. Question 4—No. Question 5—No.

Illinois—Jas. A. Egan, Sec. State B. O. H. Question 1—Communicable. Question 2—No, only as regards cattle. Question 3—Yes. Bill also failed last session; asked for \$200,000 for state hospital for tuberculosis. Question 4—No. Question 5—Exceedingly difficult to do so.

Florida—Jas. Y. Porter, Sec. State B. O. H. Question 1—Yes. Question 2—No. Question 3—No. Question 4—Church and Hospital Orlando. Question 5—No.

Indiana—J. N. Hurty, Sec. State B. O. H. Question 1—Yes. Question 2—No. Question 3—No. Question 4—No. Question 5—No.

New Hampshire—J. A. Watson, Sec. State B. O. H. Question 1—No. Question 2—No, except cattle. Question 3—No. Question 4—No. Question 5—Incomplete.

West Virginia—A. R. Barbee, Sec. State B. O. H. Question 1—No, but B. O. H. so considers it. Question 2—No. Question 3—No. Question 4—No. Question 5—No.

Arizona—W. L. Woodruff, Sec. State B. O. H. Question 1—No. Question 2—No. Question 3—No. Question 4—No. Question 5—No.

New York—B. L. Schultz, Sec. State B. O. H. Question 1—Yes. Question 2—Yes. Question 3—Yes. Question 4—Saranac, N. Y.; Liberty, N. Y. N. Y. City hospitals. Question 5—Nearly 13,000 deaths yearly.

Delaware—Alex. Lawber, Sec. State B. O. H. Question 1—No. Question 2—No. Question 3—No. Question 4—No. Question 5—Higher than for any other disease.

Idaho—R. L. Naroe, Sec. State B. O. H. Question 1—No. Question 2—No. Question 3—No. Question 4—No. Question 5—No.

Nevada—S. A. Gibson, Sec. State B. O. H. Question 1—No, except cattle. Question 2—No. Question 3—No. Question 4—No. Question 5—No.

California—W. P. Mathews, Sec. State B. O. H. Question 1—No, but B. O. H. so regards it. Question 2—No, except municipalities. Question 3—No. Question 4—No. Question 5—Incomplete.

Alabama—Geo. P. Waller, Sec. State B. O. H. No reply to either of two letters.

Missouri—L. C. McElivee, Sec. State B. O. H. No reply to either of two letters.

Georgia—J. B. S. Holmes, Sec. State B. O. H. No reply to either of two letters.

Tennessee—J. A. Albright, Sec. State B. O. H. No reply to either of two letters.

## CONSIDERATION OF SOME IMPORTANT SUBJECTS CONNECTED WITH THE TREATMENT OF PNEUMONIA.\*

EDWARD F. WELLS, M.D.

CHICAGO.

In assuming the duties pertaining to the presidency of this Society I should indeed be lacking in that kindly spirit of gratitude which is usually inherent within us were I to fail in embracing this opportunity to express my sincere thanks for the honor which you have conferred upon me. This office is assumed with diffidence and a keen sense of the important obligations which it entails, and I can only assure you that there shall be brought to bear upon it, unreservedly, all the energy and talent which is mine to give. This Society has been fortunate in having had at its head during the past three years such an indefatigable worker as my predecessor, and my efforts shall be directed toward maintaining, as far as lies within my power, the Society upon the high scientific and practical plane to which it has been raised. In this matter I shall hope to merit, and to receive, the hearty, coöperative, active support of every member of our Society.

Although the treatment of pneumonia has been for generations the chosen battlefield of therapeutics, and the subject is being constantly offered for discussion in our medical societies, nevertheless I am of the opinion that the last word upon it has not yet been spoken, and that interest in it is far from being exhausted. On the

\* Being the Presidential Address of the Chicago Society of Internal Medicine.

contrary I believe that the time is now opportune for a careful and analytical consideration of certain important problems in this field which are as yet unsolved. It is but fair to state that time will permit the presentation, in a cursory manner, of only a few of these.

The fact that pneumonia is increasing in prevalence is *prima facie* evidence that prophylactic measures have either not been adopted or have proven unavailing. As a matter of fact they have not been employed by the few, except in rare instances, and have not been even considered by the many. Is this as it should be? Have we at hand sufficient evidence to lead to the conclusion that any individual or communal prophylactic measures offer reasonable prospects of usefulness, and, if so, in what do they consist? Let us rapidly review our fundamental knowledge bearing upon this point.

#### ETIOLOGY.

Pneumonia is caused by a specific pathogenic micro-organism, the pneumococcus. The pneumococcus will not grow in acid media, and in its growth it produces an acid and an albumose, which in turn probably cause the death of the organism. Its different strains vary in virulency, and somewhat in biological characters. Pneumococci from individual strains vary in virulency as they are grown in differing media, as, *e. g.*, the diplococcus found in the nasal passages of a pneumonic patient is less virile than that found in the inflamed lung, but the germ of lesser virulency may be made intensely active by being passed through a susceptible animal. Its capsule is lost by cultivation outside animal bodies. It is not destroyed by most of the ordinary antiseptics and its capsule is only acted upon by alkalis and ethers. Contrary to popular belief it may lead a saprophytic existence. The pneumococcus is present in some part of the upper respiratory passages in a very considerable proportion of healthy persons, and it is probable that pneumonia is ordinarily due to the aspiration and slipping down into the alveoli of some of these ready at hand cocci.

#### PROPHYLAXIS.

In view of the foregoing and other relevant facts we may, tentatively, formulate the following prophylactic rules: All discharges from the respiratory passages should be treated in such manner that they can not gain access, in the form of spray or dust, to the respirable air. Pneumonic sputum should not be allowed to become dry, and should be burned. The tenacious, clinging expectoration should be carefully removed from the lips, teeth, etc. The mouth, throat and nostrils should be cleansed at proper intervals with an acid solution, followed, after a few minutes, with an agreeable mildly alkaline antiseptic solution. With reasonable care along these lines it is probable that the infected person may jeopardize only very slightly the safety of those who come in contact with him.

#### VIRULENCE OF THE TOXINS.

To the careful and experienced clinical observer it is quite clear that the course and termination of pneumonia varies within wide limits, due to a variety of causes, among which may be mentioned, as being of greatest importance, the special virulency or benignity of the strain of the pneumococcus, and that intangible and peculiar, but positive and widespread impressionability of the populace which our grandfathers in medicine very aptly called the "prevailing medical constitution" or "epidemic influence." This remarkable susceptibility upon the part of the inhabitants of a more or less extensive district to receive and afford a congenial soil for the

pneumococcus, in which it may attain extraordinary virility, is a condition which must be constantly reckoned with in the prognosis and treatment of pneumonia.

In pneumonia the patient's life is threatened from many and diverse directions, all of which can neither be appreciated nor mentioned. A few of these, however, deserve our present consideration: The chief element of danger is from the introduction of the pneumococcal toxins into the nutritional fluids of the body. This is one of the most powerful of the bacterial toxins, as may be inferred from the profound chill and raging fever which follows the initial introduction into the system of an infinitesimal quantity of the poison, and this diluted almost beyond conception. That the system becomes less impressionable and more resistant to the toxin as the malady advances is evident from the fact that progressively increasing quantities of toxins absorbed do not produce correspondingly more pronounced effects. This may be due to a variety of causes, as, *e. g.*, simple accommodation to an irritant; physical protection by the retention, to a considerable extent, of the toxins within the blood-vessels; by dilution of their poisonous solutions; their absorption and modification by leucocytes or other cellular elements; the neutralizing and protecting influence of antitoxins or defensive secretions generated by the leucocytes or other cellular elements, or to antitoxins evolved by the pneumococcus itself, etc.

Can we assist Nature along these lines? I answer, unhesitatingly, that we may do so. But in making any attempts in this direction we should act with conservative discretion and only after careful consideration of as many of the facts in the case as may be made manifest. These problems are inherently complex, and are rendered especially difficult by the instability of the factors which enter into them. We also lack the results of the right kind of experimental and clinical investigation in these fields. It behooves us, therefore, to be very careful that, by misdirected effort, we do not increase the dangers of a serious malady.

#### CAPILLARY PARESIS.

One of the early and persistent symptoms of pneumonia is capillary paresis. The blood, with each ventricular systole, is forcibly impelled through the capillaries into the veins. It results from this that the arterial system is underfilled, while the venous system is overfilled with blood; and the fluids without the blood-vessels, not receiving fresh supplies by osmosis through the capillary walls, are more or less stagnant. This is probably an efficient device of Nature for protecting the dynamic tissues of the body from the irritating and paralyzing effects of the pneumococcal toxin; but it necessarily follows that those tissues will be insufficiently nourished and be exposed to the deleterious influences of being constantly bathed in a solution of their own cellular waste. In addition, when this waste-laden fluid later finds its way into the general circulation and is distributed throughout the body it may become itself an element of danger. Now, under these circumstances, shall we interfere, and if so in what manner? To this I would answer, that in the ordinary case I believe we should, and as follows: Early I would give a mercurial, followed by a saline cathartic; bleed to 500 or 750 c.c.; induce a rather free perspiration; give fluids freely; give digitalis and adrenalin hydrochlorate in efficient doses. By these procedures from 6 to 10 per cent. of the toxin in the blood vessels is removed, and that which remains is very considerably diluted; the capillaries are stimu-

lated to contraction, osmosis is increased, the bodily tissues are nourished and their waste products are speedily removed; the heart, instead of wildly beating against a partial vacuum is steadied by meeting a normal resistance. A second bleeding, later in the course of the disease, but anticipating obviously ominous symptoms, may distinctly turn the tide toward recovery.

#### LEUCOCYTOSIS.

In pneumonia there is a very marked leucocytosis, which has certain suggestive characteristics; *e. g.*, it appears simultaneously with, or follows within a few minutes after the initial chill; the polynuclears are absolutely increased, usually many fold; the eosinophiles are practically driven out of the peripheral circulation, to reappear with the earliest evidences of decline in pathogenic activity. That leucocytosis plays an important protective rôle must be acknowledged by anyone who gives the subject any observing and reflective study, although the exact nature of this defense remains, as yet, unknown. It is clear, however, that whatever is done is accomplished by those mobile secretory glands, the polynuclear leucocytes, discharging their neutral, or faintly alkaline secretion into the liquor sanguinis, and that this secretion combines with and neutralizes the pneumococcal toxins, or, possibly acts upon the tissues of the body in a manner to make them more resistant to the poison. Now it happens that in some cases there is but little or no leucocytosis, and experience abundantly shows that, although all cases accompanied by an increase of leucocytes do not recover, an exceedingly large proportion of those in which leucocytosis is absent die. Can we assist Nature in this field by stimulating the activity of the polynuclear leucocytes and by inviting them to invade, in force, the sanguineous current? It is my belief that this may be beneficially accomplished by the administration of nucleinic acid, and this I prescribe in every case in which a satisfactory leucocytosis fails to appear.

Nucleinic acid may be beneficial, also, in preventing cardiac and vascular thrombosis. This is offered, at the present time, only as a suggestion. Certain it is that in a short series of cases in which this agent was used the blood platelets were less numerous and the coagulability of the blood was less than in another series in which nucleinic acid was not employed. My observations, however, are far too few in number to serve as a basis for formulating a plan of treatment, having in view the object named, and the question can only be decided by further experience. Because of their known tendency to cause coagulation of the blood, lime and gelatin should not be given in pneumonia.

#### ANTIPNEUMOCOCCIC SERA.

The pneumococcus speedily dies in any culture medium, and its death is probably due to the toxins produced. We know that the human system appears to accommodate itself, somewhat, to the poison after the first onslaught of the disease. We also know that the symptoms rapidly subside at a time which corresponds to the greatly diminished virility or death of the cocci within the affected alveoli, and, consequently, at a time when presumably but little of the toxin is finding its way into the sanguineous current. Animal experimentation with dialyzed toxins, the glycerinated extract of dead and dried bodies of the pneumococcus, the serum from pneumonic patients, and the serum from animals which have been subjected to long continued pneumococcal inoculations have, so far, been inconclusive, as to their prophylactic or curative powers; and clinical experience with

the various sera which have been placed upon the market, in such an honorable manner, has been equally inconclusive. Certain it is that with an eagerly receptive medical mind they have failed to find that favor which is quickly and enthusiastically awarded every therapeutic novelty of real value. My own experience in the use of such sera has been too limited to be of any use in forming any conclusions, and the opinion expressed is that formed after a somewhat careful study of the literature upon this subject. I am free to say, however, that I have witnessed phenomena following the hypodermic injection of such sera which leads me to believe that they are agents of real and beneficent power. For example, in one case the injections were followed by the reappearance in the blood, while the disease was yet at its height, of those harbingers of subsiding toxemia, the eosinophile leucocytes. Analogy leads us to believe that a useful antipneumococcal serum may be produced, and I am hopeful that this will be accomplished.

#### USE OF CHLORID OF SODIUM.

One of the most remarkable of the pneumonic phenomena is the great diminution of, or disappearance from the urine, of the chlorids. It is probable, if not certain, that these are required in the blood, in the intra-vascular fluids of the body and in the alveolar exudate for purposes of defense against the pneumococcal toxins, or the parasite itself. If this is probably, or even possibly, true there is presented sufficient reason for the systematic use of chlorid of sodium as a therapeutic agent. In my own practice I direct that all foods, including, especially, milk, shall be well salted, and that saline enemata be given as freely and as frequently as they can be retained and absorbed. If patients are treated, systematically, in this manner, it will be found that, as a rule, the chlorids will not be entirely absent from the urine; and this may be taken as evidence that the system is being supplied with somewhat more chlorids than is necessary to meet its requirements.

#### UNCONTROLLABLE FETID DIARRHEA.

One of the late symptoms, in some, happily rare, cases of pneumonia which is certain to strike terror to the heart of those who are aware of its serious import, is the sudden onset of an uncontrollable fetid diarrhea, which may become involuntary and usually ends only with the patient's death. Often the appearance of such a diarrhea is entirely unexpected, although it is merely the culmination of a preceding intestinal sepsis which could have been detected, and probably corrected, if it had been looked for. In my opinion no case of pneumonia is properly managed in which careful and frequent investigation of the functional activity of the gastro-intestinal tract is not made. A parietic state of the intestines, with tympanitic distension and an inability to pass flatus should be recognized at once and proper relieving measures applied; indeed, this condition should be anticipated and prophylactic management should be the rule from the earliest period of the attack. In these cases the sulphates of the urine are always increased, sometimes to an enormous extent; *e. g.*, I have seen the 24 hours' urine contain the equivalent of more than 320 grains of sulphuric acid. In one case of this kind which I have had recently under observation there were present a large number of nucleated erythrocytes, and the blood was literally swarming with those small, deeply colored, lenticular bodies known as Eichhorst's corpuscles; but the significance of these hemic changes is not apparent. The management required to prevent these undesirable and dangerous conditions resolves itself into the regular and

thorough evacuation of the bowels; the proper regulation of the diet; and the administration of some efficient intestinal antiseptic, as, *e. g.*, salol.

#### OXYGEN

It has been said that, in pneumonia, one of the most ominous of the physical signs is the presence in the sick-room of an oxygen outfit! In consultation practice this may be true, but I do not believe that the implied stricture is fairly applicable to ordinary family practice. Indeed, I believe that the employment of oxygen inhalations, begun early—certainly at the very beginning of that slight but steadily progressive increase in frequency and shallowness of breathing which the experienced physician so dislikes to see—and frequently and freely given, is a useful measure, and is one of the many things which may sometimes save a life which, otherwise, might be lost. I am not able to give any reasonable explanation as to how or why oxygen acts beneficially in these cases except the unsatisfactory one that it is a respiratory stimulant. Nevertheless, I use it, along with strychnia, caffeine, camphor, morphin, etc., each of which agents, properly employed, are of the greatest value.

#### RAPIDITY OF CHANGE.

In typical cases of pneumonia there are three striking features which have always attracted the attention of clinical observers. I refer to the sudden and furious onset which transforms, in a few hours, the man of robust health to one prostrate with serious illness; the rapid subsidence of the acute symptoms at the time of crisis, by which he passes, again in a few hours, from a raging storm of morbidity to a state of comparative well-being; and the unexpected celerity with which the collapse which speedily ends in death appears upon the scene of apparently satisfactory progress. These rapid transformation scenes are, however, peculiarly characteristic of pneumonia, and the observant physician will have early noted that, from first to last, the clinical changes occur with remarkable suddenness. This leads me to advocate, with all the earnestness which I possess, that pneumonic patients be given careful, observant, intelligent and unremitting attention. They should be visited at frequent intervals or, in some cases, be given constant attention. I have had occasion, in more than one instance, to feel that the patient's recovery was due to the fact that the physician was present and prepared to act at the moment unfavorable and portentous conditions arose, and I am convinced that, in many cases, if such medical attention is not given, the patient is being deprived of some of the resources of our art, and that his chances of recovery are thereby directly lessened. It is scarcely necessary to remark, in the presence of this audience, that, in addition to the observations which were formerly made by every physician, the practitioner of to-day must bring to bear upon his case, in an intelligent manner, and in detail, and often, all the diagnostic resources of our time, including those of the clinical laboratory. In especial should his attention be directed to the state of the heart and capillaries; the urine; the blood; the nervous reflexes. The nursing and surroundings of the patient should be of the best which his means can procure, for I am sure that in but few positions of peril can the beneficent power of money be shown to better advantage than in a well-generalized combat with pneumonia.

**Paraffin Prothesis.**—Herczel states that he has prevented or cured prolapse of the rectum in a few cases by Gersuny's injections of paraffin. He has also thus cured a vesico-vaginal fistula, etc.

## CASES OF SARCOMA AND OF HODGKIN'S DISEASE TREATED BY EXPOSURES TO X-RAYS—A PRELIMINARY REPORT.

WILLIAM ALLEN PUSEY, A.M., M.D.

Professor of Dermatology in the Medical Department of the University of Illinois.

CHICAGO.

#### SARCOMA.

**CASE I.**—This case was referred to me by Dr. A. J. Ochsner, Professor of Surgery in the University of Illinois. The patient entered Augustana Hospital in Dr. Ochsner's service August 18, 1901, when the history, of which the following is an abstract, was obtained: J. L. B., aged 24, clerk, had the ordinary diseases of childhood, otherwise he has always been well. He has not had syphilis. The family and personal history is without significance. Six months ago—February, 1901—he noticed a small hard swelling the size of a filbert below the angle of the jaw on the left side of the neck. This gradually increased in size. Ten weeks ago—May, 1901—he noticed a similar hard swelling the size of a filbert on the right side of the neck about an inch below the mastoid process. This has increased in size rapidly. During the past week he has been troubled with morning headaches, usually relieved by taking food.

**Present Condition:** He is a fairly well-nourished, spare-built man. A loud harsh murmur accompanies and follows the first sound of the heart. The lungs are normal. There is a hard, freely movable swelling the size of a hen's egg just below the angle of the jaw on the left side, which is not tender or painful. There is another hard mass underneath the upper third of the sterno-cleido-mastoid muscle on the left side, which is not freely movable, nor tender or painful. There is a very hard mass on the right side of the neck below the ear and mastoid process the size of a man's fist, which is not freely movable, nor tender or painful.

The clinical diagnosis of sarcoma was made by Dr. Ochsner and the tumors on the left side were removed August 19. The tissue was sent to Dr. Robert Zeit, Professor of Pathology in Northwestern University School of Medicine, for microscopic examination. Dr. Zeit's diagnosis was "small round-cell sarcoma." The patient made a prompt recovery from the operation and on September 2 was sent to me for a month's exposure to x-rays preliminary to a second operation. The left side showed a healthy scar. The condition of the right side of the neck at that time is shown in the accompanying photograph—Fig. 1—which, however, fails to show the full extent of the tumor. The swelling extended from in front of the angle of the jaw to within an inch of the posterior median line, and from the mastoid process almost to the clavicle. It was rapidly increasing in size. It was very hard, not freely movable and was now tender. The neck was almost rigid from the interference of the tumor with motion. The circumference around the neck over the tip of the chin, the apex of the tumor and the lower border of the hair was 21 inches.

The patient was put under x-ray exposures immediately, and these were continued from September 2 to September 27, during which time he got 21 exposures, with a hard tube and a weak light. The distance of the tube from the surface was maintained at 5 cm. and the length of the exposures varied from ten to fifteen minutes. Slight erythema appeared on September 17, and by September 27 this had developed into pronounced dermatitis, when the exposures were stopped. Within the next six days the dermatitis increased considerably and the surface became dark red, tender and denuded of horny epidermis. After this the dermatitis rapidly subsided and by October 12 was practically well. The effect of the exposures upon the tumor was almost magical. Within ten days it had shrunk perceptibly and

the motions of the head were freer. On September 17 the circumference around the chin was reduced to 17½ inches, a decrease of 3½ inches. On September 25 this was 16¾ inches and the tumor was reduced to the size of an olive. On October 11 there was no trace of the disease left except a small, freely movable, painless gland not larger than an almond kernel. There was no swelling, and all stiffness and interference with motion had disappeared. The condition October 11 is shown in the accompanying photograph—Fig. 2. On October 27 he reported to me as follows: "The gland you described as as large as an almond pit seems to be going away. It is not as solid as it was and I can move it freely. I have started to work." On December 7 he writes that as far as he can tell this side of his neck is as well as it ever was. The gland, he thinks, is now about half the size of an almond pit, and he can find it only by careful

with symptoms of sarcoma of the bladder. There was profound cachexia and evidences of general sarcomatosis. The patient was put under *x*-ray exposures, chiefly with the hope of relieving his pain. He was given 16 exposures without any effect upon the tumor, but according to his voluntary statement with considerable relief from pain. With my approval the treatment was discontinued.

CASE 3.—Woman, age 60, with extensive inoperable sarcoma involving the right pectoral muscles and the right shoulder. She has been under treatment for a month with perhaps small shrinkage in the tumor. She was suffering from severe pain when the treatment was begun and was running down in strength. According to her statement her strength has increased considerably and there is great relief from pain. Her physician, Dr. William Fuller, of the University of Illinois, who referred the case to me, tells me that there is no doubt about the great relief from pain.

The second and third cases are reported, of course,

Figure 1.

search. This report is repeated in a letter of January 12. He also reports that since September he has gained 12 pounds in weight.

We have here then a clinical diagnosis of sarcoma by Dr. Ochsner and a microscopic diagnosis of small round-cell sarcoma by Dr. Zeit. There can not be the slightest doubt that the tumor on the right side of the neck was of identical character with that on the left, so that the diagnosis of this tumor must be small round-cell sarcoma, a highly malignant variety of the disease. Under *x*-ray exposures alone—for the patient was given absolutely no treatment except *x*-rays—this sarcoma was made to disappear, and after three months without treatment it has not shown any evidence of recurrence.

CASE 2.—Man, age 67, osteosarcoma of the right shoulder.

Figure 2.

simply that my record may be complete. The third case shows as yet nothing except some evidence of relief from pain, which is usually the prompt result of the use of *x*-rays in malignant neoplasms. The second case must be set down as a failure against the method, and yet I believe it may be fairly claimed that this case had reached a stage of the disease which will probably prove beyond relief by any local method of treatment that will ever be devised.

In the first case I believe the definite effect of the *x*-rays on a sarcoma is demonstrated as conclusively as a demonstration can be made in medicine. There is no link lacking in the evidence in this case of the effect of *x*-rays on a sarcoma. It is impossible to believe that the disappearance of this sarcoma was simply a coincidence

with the exposures to the rays. At the time the treatment was begun the tumor was growing rapidly, and its subsidence was *pari passu* with the accumulation of the effects of the rays. The patient had no intercurrent disease, such as an erysipelas, to account for the disappearance of the tumor and he had absolutely no other treatment. This is, of course, only one case, but the result is so startling that it must command one's interest. The case is not unique, although I do not recall another case in which the result was so complete. There are several authentic reports in the literature showing the favorable influence of *x*-rays on sarcomas, and bearing this in mind, I believe it may be maintained that in cases of sarcoma, which can not for any reason be treated successfully by surgical means, the effect of *x*-rays should be tried; and, further, in cases of sarcoma which have been treated surgically subsequent use of *x*-ray exposures

graph—Fig. 3. There was a mass of glands on the left side as large as a fist. Under *x*-ray exposures the swelling rapidly subsided, and in two months the glands were reduced to the size of an almond. The child has had intermittent treatment from November, 1901, to the present. There are a couple of cervical glands on the right side as large as a filbert, but they have shown no tendency to enlarge and there is no swelling. The condition of the patient January 8 is shown in the accompanying photograph—Fig. 4.

CASE 2.—Man, age 50, was referred to me by Dr. L. L. McArthur, surgeon to St. Luke's Hospital. About a year and a half ago the patient noticed enlargement of the axillary and epitrochlear glands on the right side. Both glands rapidly increased in size. The diagnosis of Hodgkin's disease was made by Dr. McArthur, and for some time the patient was under treatment with paren-

Figure 3

ures as a prophylactic is a procedure which should be considered.

#### HODGKIN'S DISEASE.

In this connection I wish to refer briefly to two cases of pseudo-leukemia which I have under treatment by *x*-rays.

CASE 1. Boy, age 4, referred to me by Dr. Ochsner. December, 1900, the mother noticed a swelling in the cervical glands on the left side and soon afterwards a similar swelling on the right side. These steadily increased in size up to August, 1901, when Dr. Ochsner made a diagnosis of Hodgkin's disease and removed the glands on the right side. On September 11 he referred the case to me for exposure of the glands on the left side of the neck. The condition at the time that the patient came to me is shown in the accompanying photo-

Figure 4

chymatous injections of arsenic, in spite of which the tumors steadily grew. On November 19 I undertook the exposure of the epitrochlear gland, while Dr. McArthur continued the arsenic injections in the axillary gland. At the time that *x*-ray treatment was begun the epitrochlear gland was almost as large as a goose egg and very hard. Within a month it was reduced to about one-third its previous size, and at the present time it is about as large as an olive and is quite soft. In the meantime the axillary gland under the arsenic injections showed no change, and on December 18, at Dr. McArthur's suggestion, I began exposures over that gland. It was then as large as a child's head and very greatly interfered with the motion of the arm. The patient insists at present that the gland is smaller and softer, and that he can use his arm very much more

freely. As an illustration of this, he is able to play billiards again, a thing he has not recently been able to do.

103 State Street.

# SURGICAL CORRECTION OF MALFORMATION AND SPEECH DEFECTS DUE TO OR ASSOCIATED WITH HARE-LIP AND CLEFT PALATE.\*

GEORGE V. I. BROWN, A.B., D.D.S., M.D., C.M.

Professor of Oral Surgery, Milwaukee Medical College, and Oral Surgeon, Trinity Hospital.  
MILWAUKEE, WIS.

The purpose of this discussion is to make clear advantageous possibilities in the treatment of hare-lip and cleft palate by a new method which, 1, reduces the width of the fissure and thus renders a subsequent operation for closure by operation upon the soft tissues more certainly successful and more beneficial by preserving the usefulness of the soft parts; 2, by readjustment of the unequally developed bone structures, gives a more perfect contour to the form of the face after operation; 3, makes it possible to operate successfully upon patients almost with regard to age limitations. The objects which make relief of some kind desirable if not imperative for patients so afflicted, whether the method of procedure be surgical or prosthetic, may be summed up in the two considerations, health and speech, for the purpose of all treatment must be directed toward improvement in one or both of these requisites. Malformations of this nature affect the general health of individuals chiefly in two ways, by malnutrition due to inability of infants to take sufficient nourishment properly, which interferes with normal development sometimes to so great an extent as to place the lives of such children more or less in jeopardy, and nasal catarrh caused by irritating secretions, bacteria and foreign matter which gain access to the nasal passages through the opening from the oral cavity, or constant exposure of the nasal mucous membrane to external irritants. This diseased condition usually extends to the pharynx and carries in its train many associated disorders that affect the adjacent frontal maxillary and ethmoidal sinuses, involving also the nervous and circulatory disorders.

In classifying cleft palate cases, the first division recognized between acquired and congenital cases is important but quite insufficient, and much depends upon a correct and distinct classification of subdivisions under these two heads, which will facilitate an intelligent understanding of the nature of each division, its relation to the particular kind of treatment required and the special difficulties each presents that must be overcome in effecting a cure. Strangely enough, there seems to be little or nothing especially clear or valuable in this direction to be found in literature upon the subject.

Acquired cases have one of two etiologic factors: disease or accident. When the tissues of either soft or hard palate are destroyed by pathologic condition, naturally the advisability or inadvisability of an operation would be determined by the nature of the cause. For instance, in syphilitic cases, operation would usually be contra-indicated, because of the tendency to still further loss instead of restoration of tissue. If the opening be confined to the hard palate, as frequently occurs from necro-

sis, such an opening is much more easily and better covered by a nicely-fitted denture, but if the tissue of the soft palate has become involved, speech is impaired to such a degree that more or less risk is warranted in the hope of restoring the ability to speak distinctly.

Figure 1.

Classification of congenital cases presents difficulties which can best be understood by considering them with regard to the nature of the deformity, since there are such notable differences between typical forms of

Figure 2.

congenital fissures of the palate and lip, each with its own characteristic difficulties to combat in treatment, and again, in order that the surgeon may intelligently undertake their correction, it is necessary that

Figure 3.

another distinction be made with due regard for the vital question of age in relation to operative procedures. Under 1, we distinguish clefts in the soft palate with hard palate normal; 2, a continuous separation through both hard and soft palates; 3, double cleft, which may

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee.

bifurcate from a single one at the intermaxillary bone, or may make two continuous fissures through hard and soft palates. Age requires recognition by the following divisions representing distinct operative differences: 1, infants for whom immediate operation may become necessary on account of inability to obtain proper nourishment; 2, eight to ten months old; 3, after the decidu-

Figure 4

ous teeth have erupted but before habits of speech are fully established; 4, older children and adults after the eruption of permanent teeth.

#### HIGH MORTALITY IN INFANCY.

The danger and high rate of mortality recorded after infants have been operated upon are too well understood among surgeons to warrant an extended discussion, for

Figure 5

whether the death rate be 50 per cent., as given by Ehrman, or something less, as stated by Sched, Wolff, Fowler and other writers, it nevertheless goes without saying that if good results can be obtained by operation performed when the child has gathered power of resistance, the method which can accomplish this result must be the better method. So long as it was claimed that

in order to have perfect union of the parts and anything like a perfect development of speech afterward it was absolutely essential the operation be performed in early infancy such operations might then be excusable, but while it must be admitted that infants take chloroform with comparatively little danger, and that they do not suffer shock through fear of danger the nature of which

Figure 6

they are unable to comprehend, it is only too true that they bear the loss of blood badly. In such cases, with the mouth full of wires and sutures, the inducement to take nourishment through the mouth is not very great. In fact, rectal feeding must almost invariably be resorted to because the digestive tract suffers more or less disturbance from bacteria, from the wound surfaces and in various ways. If nourishment per rectum can be continued and vitality of the child sustained until the stomach and intestinal tract are sufficiently restored to per-

Figure 7

form their normal functions, success might reasonably be expected, but too often irritation of the rectum interferes before the activity of the digestive organs is restored; then and frequently does the prognosis become exceedingly grave.

#### CHILDREN AGED SEVEN TO EIGHT MONTHS.

When the child has passed through the first seven or eight months of infancy and is upon a fairly secure vital

basis, the treatment preparatory to a future operation for hare-lip can best be given by the method shown in illustration, Fig. 1. and the reasons why such preparatory treatment is necessary by Figs. 1, 2, 3, 4, 5, which portray the unequal development that is invariably found

decidedly uneven appearance to the face. Since on one side the bones of palate protrude while upon the other there is a corresponding recession. To overcome this a heavy wire suture is passed from the buccal surface upon one side directly through both portions of the jaw to

Figure 8.

in these cases. If no such preparatory treatment be given there will be a less perfectly shaped mouth, because of the extreme tension due to an effort to make the tissue bridge such a wide space, and a flatness of the mouth, be-

Figure 10.

the buccal surface of the other, drawn closely and fastened at each side with little silver plates to prevent it pulling through—see Fig. 1. The direction of this wire is governed in such a way that when it is slightly twisted in the center of the mouth from day to day the

Figure 9.

cause there is no bone structure behind it, also a flatness of the ala of the nose upon the affected side, with deflection of the nasal cartilage to the opposite side, giving a markedly irregular appearance to nose, lip and face. This is due to the fact, very clearly noticeable in the pictures referred to, that arrest of development of the jaw upon one side or the other causes a

Figure 11.

tension will bring forward one side and draw back the other. This force, while gently and regularly exerted, is sufficient to alter the form of the bones in any direction desired, at the same time it brings the two sides of the cleft nearer together and reduces the difficulty of the future operation upon the palate quite materially. When the proper form of adjustment has been secured in this

manner operation for hare-lip can be performed very easily and perfectly, because the space to be covered has been reduced to the minimum. The nose and bones of the face are thus straightened, and in all respects the result is more perfect than could otherwise have been accomplished. This is shown in Figs. 4, 5, 6, which are pictures of the same baby and cast of his mouth before operation. The wires can then be removed, because the tension of the lip muscles will continue to exert a force, which will prevent widening of the cleft in the palate that would otherwise take place and continue to narrow it. Thus the operations of uranorrhaphy and staphylorrhaphy become much simplified and can be performed at any period that may seem most favorable to the circumstances and condition of the patient. Figs. 7, 8, 9 portray in some degree the appearance of a child for whom the unopposed muscles had pulled the detached intermaxillary bone until it stood out in such a way as to appear to be a continuation of the nose, from the end of which two teeth were being erupted. In this case a little more than an inch of the projecting bone

Figure 12

was resected, the borders of the jawbone on each side freshened, the intermaxillary forced back to its natural position and wired to the lateral portion of the jaws; operation for double hare-lip was then performed, with the result shown in Fig. 10. By removing a section from the middle of the bone instead of cutting off at the end to restore the defective form of the face and lip the erupting deciduous teeth, together with the germs of permanent ones, were preserved, and we know as the child becomes older the development of these teeth will give to face and jaws an almost perfect contour instead of the deformed appearance which would otherwise have resulted.

#### CHILDREN WITH DECIDUOUS TEETH.

The care of cases of the third class is illustrated by Fig. 11. In these the deciduous teeth form attachments, to which are cemented metal bands that hold the appliance, which consists of a nut and bar with a thread cut upon it, so that all the different parts are brought into place by turning the nut slightly several times a day, such a pressure being brought to bear that the parts

upon each side are drawn towards each other. In children of this age the bones yield readily, and in a few days, without pain or serious inconvenience to the child, the two sides of the cleft can be approximated so closely that when a bur in a surgical engine is passed along between the two borders it will cut off the soft tissue and also freshen the borders of the bone. The parts can then be screwed tightly together and the hard palate given opportunity to unite without fear of sloughing, with the result that a complete bony union is secured, which in most cases can be depended upon to include all that portion of the cleft from the first deciduous molars forward. The benefit of this is apparent because of more complete circulation, which renders the later operation to be performed for closure of the posterior portion of the cleft and the soft palate much less likely to be unsuccessful than it would be under other circumstances. Beside this, the space is so much narrower than would otherwise be the case that the operation is in all respects so simple as to make a good result comparatively certain. Again, with the bones united, we know that after the permanent teeth are erupted an orthodontia appliance which will exert pressure in ex-

Figure 13

actly the reverse direction from the one used in reducing the cleft will widen the arch again to normal and even perfect form. Fig. 12 shows No. 11 after operation; Fig. 13 shows the case of a little boy who had been operated upon five or six different times unsuccessfully by other methods, but whose palate fissure was easily reduced by this method in a very short time.

(To be continued.)

#### Prizes Awarded by the Paris Académie de Médecine.—

Among the foreigners who received prizes at the annual ceremonies of the Académie, were Miss Lipinska, M.D. of Odessa, Russia, for her work on the "History of Medical Women from Antiquity to Our Day"; Dr. H. Christiani and Madame A. Cristiani, M.D., of Geneva, received the Louis prize of 3000 francs; Dr. Zinno of Naples, 600 francs; Dr. Dalla Vedova of Rome, for an article on the "Pathogenesis of Simple Ulcer of the Stomach," and Dr. E. Ehlers a prize without money for his historical work on the "Leper Hospitals of the Middle Ages." Dr. Remlinger of Constantinople also received part of a prize. Most of the prizes were divided and an "encouragement" of 1000 francs was given to Professor Carrière of Lille from the great Audiffred tuberculosis prize.

# TRAUMATIC ARTERIO-VEINOS ANEURYSMS OF THE SUBCLAVIAN VESSELS,

WITH AN ANALYTICAL STUDY OF FIFTEEN REPORTED  
CASES, INCLUDING ONE OPERATED UPON.

RUDOLPH MATAS, M.D.

NEW ORLEANS.

(Continued from page 107.)

## OPERATION.

On Sept. 13, 1900—the ninth day after injury—after all preparations had been completed, and with the valuable assistance of Drs. H. B. Gessner, S. M. D. Clark, John Smyth, U. Maes, and Dr. Power, who acted as recorder, the operation was undertaken. The operation was begun at 9:20 a. m., and it was 2:30 p. m.—nearly five hours—before the patient was taken back to his bed, though the actual operative work did not consume three hours. Much of the time was consumed in giving the patient periods of rest, especially during the local anesthesia stage of the operation. During these rest periods, as is often done in tedious operations under local anesthesia, the patient was given freely of ice water, panopepton, toddy, and even beef tea, all of which he enjoyed immensely, and helped him greatly to control himself. Even after chloroform had been administered he was never fully unconscious, except for a few moments, and would frequently rouse up to call for ice water or other drinks, which were given to him liberally without ever exciting nausea or vomiting. We will begin the narrative of the operation by stating that in anticipation of the long duration of this operation and of the advantages that would be gained by diminishing the risks of prolonged saturation with a general anesthetic, and with the view of diminishing the turgescence of the jugular and other cervical veins, which were already greatly distended, and would be likely to swell still more under general narcosis and vomiting, I decided to attempt the preliminary resection of the clavicle by means of local anesthesia. I was encouraged in this by the calm and fearless temperament of the patient, who showed no anxiety in the contemplation of the operation or of his surroundings. It was not my intention to perform the entire operation under local infiltration anesthesia, but simply to economize the general anesthetic by adopting infiltration anesthesia during the first stages of the operation, viz., 1, the resection of the clavicle, and, 2, the application of a provisional loop around the innominate. The advantages of local anesthesia during these two important stages of the operation were not exaggerated, as we found subsequently, because we were relieved of all anxiety and annoyance on the score of vomiting or other disturbances in breathing from cyanosis, etc., which might have caused a great turgescence of the jugular, subclavian, and innominate veins while exploring the pretracheal region for the innominate artery. As it was, the patient gave us great assistance by voluntarily changing the position of his head to suit our needs as we displaced the distended and pulsating venous trunks of the aneurysmal and cervical region. The stoicism of the patient under these circumstances, his perfect immobility and passiveness, which permitted as deliberate and free a dissection as on a cadaver, offered a truly remarkable spectacle worthy of the greatest respect and admiration.

It was not until after the provisional security loop had been placed upon the anomalous subclavian, and after a long and tedious search had been made for the missing innominate, and not until we had begun to encroach

upon the deep branches of the cervical plexus, which for obvious reasons we could not infiltrate, that he complained of pain, and we at once proceeded to administer chloroform. This was at 11:55, a little over two hours after the beginning of the operation; the general anesthetic was given in drop doses and interruptedly from 11:56 to 1:30—one hour and thirty-four minutes—after which it was discontinued altogether. It should now be stated that twenty minutes before beginning the operation the patient was given  $\frac{1}{4}$  gr. morph. sulph. hypodermically, which is usual in my practice as a routine procedure in all large local anesthesia operations.

In order to describe the operation systematically it will be divided into the following stages:

*First Stage. Section of the clavicle at the junction of the middle and outer thirds.*—For this purpose the skin overlying the clavicle and all the periosteal tissue were densely infiltrated with Schleich's No. 1 solution  $\frac{1}{5}$  of 1 per cent., eight syringefuls, each containing 22 minims, being used. The clavicle was denuded of its periosteum; two drill holes were made on each side of the proposed line of section to facilitate wiring at a later stage, and the bone was divided with a Gigli saw.

*Second Stage. Formation of osteoplastic clavicular flap.*—A curvilinear incision extending from the line of clavicular section two inches below the clavicle, including the points of penetration of the bullet, and carried across the right sternoclavicular articulation to the middle of the neck, where it terminated opposite the lower border of the thyroid cartilage.

The incision was made painless by a massive infiltration of 3.5 ounces of an isotonic saline solution of eucain B.—0.1 of 1 per cent.—dissolved in 0.8 per cent. salt solution along the whole line of incision, causing complete edema of the infiltrated points. This was injected with my special infiltration apparatus. The whole surface was covered with an aseptic ice and salt poultice, which was kept in place eight minutes. The skin, subcutaneous tissues, and clavicle and sternomastoid tendon, previously mobilized by section, were now elevated and the sternoclavicular joints disarticulated, after previous peri- and intra-articular infiltration of the tissues of joint with Schleich's cocain sol. No. 1—0.2 of 1 per cent. cocain. Some pain was experienced in making traction upon the tissues of the neck while disarticulating.

*Third Stage. Dissection and elevation of osteoplastic flap formed by clavicle, skin, sternomastoid, and subcutaneous tissues.*—The flap turned up and rolled upon itself, exposing the deep cervical aponeurosis, the sternohyoid and sternothyroid muscles, anterior jugular and thyroid veins, all large and pulsating: termination of the cephalic into the subclavian was lost in a mass of densely infiltrated tissues and exudates. Time, 10:45 a. m. Pulse, 96, good; patient cheerful, but tired. Very little bleeding thus far; few ligations. In anticipation of more exhausting work a hypodermic of  $\frac{1}{100}$  gr. digitalin and  $\frac{1}{30}$  gr. strychnin were given, with a glass of ice water and 2 ounces of strong toddy. After an interval of ten minutes of rest, the operation was resumed.

*Fourth Stage. Exposure and preparatory control of the venous side of the aneurysm.*—In view of possible hemorrhage from traction and tearing, the veins while elevating the osteo-cutaneous flap high enough to clearly and freely expose the injured vessels in the region of the scalenes, it was thought the better plan to begin this stage by thoroughly exposing the venous side of the aneurysm. The subclavius muscle, which had remained in the wound, on account of the close enucleation of the clavicle, was now divided and excised. The cephalic

vein was exposed and followed to its terminus in the subclavian vein, and the turgid bunch of veins formed by the posterior scapular, suprascapular, transverse cervical, and external jugular veins was dissected out with much difficulty on account of dense adhesions, and traced to a common terminal in the subclavian. The subclavian vein was now identified, but not without some delay, because it seemed to be divided into two very distinct parts—one on the axillary side being very much smaller than the other. This small axillary part appeared to rise up in the neck, where it could be traced to an ill-defined mass of organized exudates and extravasated products, which completely masked the outlines of the scalenes. The brachial plexus, the subclavian artery, and anterior scalene were all inextricably blended in the mass, which, judging by the pulsation and intensity of the purr and thrill, must be the seat of the aneurysmal orifice. But the anatomic characteristics of the tissues were entirely lost; not even the tendon of the scalene could be made out, as it was completely incorporated in the dense and resisting mass of exudates.

The axillary portion of the subclavian vein appeared to have been dragged upward into this mass, forming an angle. See diagram.—In the proximal or cardiac side

Diagrammatic representation of arterio-venous communication after excision of clavicle. 1, Scalenus anticus; 2, scalenus medius; 3, subclavian vein; the arrows show direction of arterio-venous current; 4, internal jugular vein; 5, innominate vein; 6, axillary portion of the subclavian vein much reduced in size as a result of angular traction from adhesion of vein to scalenus, and great distension of proximal side of vein with arterial blood poured in by artery; 7, 7, anomalous subclavian artery; the innominate absent (no carotid); 8, anastomotic orifice indicated by dotted lines; St., sternum. Case of M. M.

the subclavian vein formed an enormously distended trunk, which crossed over the first rib and was lost behind the sternohyoid muscles, where it united with the internal jugular. The contrast in the size of the axillary and cervical portions of the subclavian was remarkable, and could only be accounted for by the formation of a valvular projection in the bend of the vein, where it inosculated with the artery. Catgut ligatures were now placed upon all the tributaries of the subclavian as they entered into the axillary side of the vessel, and a provisional silk ligature, not tightly drawn, was applied to the main trunk itself, on the axillary side, a short distance before its entrance into the mass covering the scalenes. The distended trunk of the subclavian vein on the proximal side was now dissected carefully at a distance from the supposed point of anastomosis, in readiness for provisional clamping or ligation when the arterial side of the aneurysm would be controlled. It was evident that any further obstacle placed on the cir-

culation on the venous side without previous arrest of the arterial circulation would have led to such strain at the anastomotic opening that it would have caused its premature rupture.

*Fifth Stage. Exploration in search of the innominate and provisional loop around anomalous subclavian applied.*—The arterial trunks on the proximal side of the aneurysm were now explored with the finger.

The subclavian artery could not be identified in the mass covering the scalenes, and all efforts were centered upon securing control of the vessel in its first division. The sternomastoid tendon at its junction with the sternum, the sternohyoid and sternothyroid muscles were freely divided at the junction with the sternum, and were retracted with the overlying skin toward the left side of the neck by passing a loop of silk thread through the musculo-cutaneous flap thus formed.

The first obstacle encountered was in the presence of the enlarged internal jugular, subclavian and innominate veins, which, upon being freed from the confining restraint of the deep cervical aponeurosis and tense muscles, immediately formed huge swollen trunks which completely crowded the field of operation.

Fortunately, the disarticulation of the clavicle and free division of the muscles of the anterior cervical region afforded a free and easy access to the contents of the superior mediastinum. Taking the internal jugular trunk as a guide, it was followed to its junction with the subclavian and to the right innominate, which was clearly identified. By carefully displacing this to one side and the trachea on the other, I expected to find the innominate artery without difficulty, but much to my surprise I failed to find this vessel. Instead of this trunk I found a very large vessel which ascended upward into the right side of the neck in the direction of the subclavian artery; but the common carotid was absent, and for the time being I was perplexed at this unexpected state of affairs. In order to satisfy myself further, I followed this anomalous vessel down into the mediastinum, and was able to trace it with the tip of the finger to the arch of the aorta. I then made a search for the common carotid in the upper part of the wound, and was much surprised to discover that this trunk was absent from its usual place, and evidently came from behind the trachea, and only reached the surface at a high level near the thyroid gland. It was evident, therefore, that there was no innominate artery, and that we were dealing with one of those comparatively rare anomalies which are familiar enough in the dissecting-room, but are extremely rare in the history of surgical ligations. It took quite a while before I could satisfy myself that the innominate was missing altogether, as I had not anticipated this anomaly. Leaving anatomic explanations for future consideration, I proceeded to place a provisional silk loop for traction on the anomalous subclavian—Rivington's plan—on a level with the sternoclavicular joint. When traction was made upon this loop the pulsation and thrill in the subclavian area and in the veins were arrested.

It evidently controlled the circulation in the aneurysm at that time. When this was ascertained, the loop was entrusted to Dr. Gessner.

By this time—11:55 a. m.—the patient, who had been most patient and calm, began to show signs of restlessness and physical exhaustion, and I decided that the time had come to give him a general anesthetic. Chloroform was administered in drop doses, and the pulse, which had risen to 114, fell to 100 immediately after the first inhalations. The patient was so tired physi-

cally and psychically from prolonged mental tension that he inhaled the chloroform greedily. It acted most happily upon him, and soothed him without producing absolute unconsciousness, which he proved by replying intelligently to our questions, making inquiries as to the progress of the operation. He never complained of the least nausea, and drank repeatedly of cold water, toddy, and even hot beef tea, whenever we stopped to give it to him. It was only when the serious hemorrhage occurred in the sixth stage that he became momentarily unconscious, and it was then, in a large measure, due to shock and exhaustion.

*Sixth Stage. Detachment of the subclavian vein from the artery at the point of injury after failure to identify the third portion of this vessel outside of the scalenes on account of mass of exudates which masked it completely. Profuse hemorrhage from the artery at the anastomotic orifice, in spite of complete control of this vessel at its origin. Final ligation of the artery on each side of the bleeding point. Closure of the venous orifice by suture without obstructing the lumen.*—This proved to be the only critical and dangerous stage of the operation. While Dr. Gessner controlled the subclavian at its origin I made an effort to dissect the artery out of the mass of exudates in which it was embedded; this was so difficult on account of inextricable anatomic confusion, caused by extravasation and exudates, that I decided to reach the artery by following the vein to the anastomotic orifice. A long forceps was temporarily placed upon the overdistended vein on the proximal, or cardiac, side of the vein and a careful dissection was begun, following the axillary side of the vein into the mass which covered the scalenes. While doing this, the vein became suddenly detached, and instantly a flood of mixed arterial and venous blood deluged the field and compelled immediate concentration upon this point to check the flow, which for a moment appeared to defy all efforts at local compression with gauze pads and fingers. Vigorous traction upon the loop around the origin of the subclavian, held by Dr. Gessner, did not control the bleeding, which evidently came from the vertebral and other collaterals into the now severed anastomosis.

The bleeding point could not be easily localized; some blood was flowing out of the detached vein, but this was easily controlled by forceps; the chief hemorrhage came from the opening in the mass of exudates covering the scalene. By the application of one finger, and then another the bleeding was finally controlled, but the least relaxation of the pressure immediately allowed it to flow in a gush. With the finger on the bleeding point, reinforced by the additional finger of one of the assistants, Dr. Maes, I made a vertical incision into the mass by the side of the finger, and succeeded in bringing to view the aponeurotic edge of the scalenus anticus, which I detached almost completely from its insertion by cutting into it from the axillary side on a level with the tubercle; the muscle was not entirely detached at its insertion for fear of injuring the phrenic nerve, but the section was sufficient to allow me to insinuate the right index into the inter-scalenal space, where I recognized a firm, flat cord, which I took to be the third portion of the subclavian artery. The vessel was now seized with a long-bladed clamp. I then cautiously removed my left index from the bleeding point on the scalene, and had Dr. Maes substitute his fingers for mine over the orifice, which he did so quickly that no blood was lost in the exchange. I was then able to trace the subclavian artery from the point where it had been grasped

by the forceps to the posterior surface of the scalene. The artery was found adherent to the posterior surface of the muscle, the bullet having perforated it in its central portion. The muscle was interposed like a diaphragm between the artery and the vein, leaving only a small opening, scarcely large enough to admit an ordinary lead pencil through it. By retracting and pulling on the outer border of the partially divided scalene, the posterior surface of the muscle could be brought to view, and the continuity of the injured artery could be established on the proximal, or cardiac, side of the vessel. Another long, narrow-bladed forceps was now placed upon the vessel just beyond the point of adhesion to the muscle, thus occluding the lumen of the vessel on the cardiac side of the perforation. When this was done, digital compression was discontinued, and we had the satisfaction of seeing that all bleeding had been arrested. A fine kangaroo-tendon ligature—Van Horn—was now applied to the subclavian artery outside of the scalene, and another of the same material, to this vessel on the inner side of the perforation, which had apparently involved three-fourths of the circumference of the artery. The artery was then divided completely at the injured point. Fearing that the proximal side of the artery had not been sufficiently secured, and that the ligature might slip because it was too close to the divided edge, another ligature was placed almost half an inch beyond the first on the inner side of the scalenus muscle. In order to do this effectively the divided or free end of the artery was seized with long-bladed forceps, and was forced to the surface through the mass of exudates which still covered and filled the right prevertebral space. The ligated stump then appeared on the inner edge of the muscle, where it was pulled out and twisted upon itself, and then ligated, as previously stated, about three-fourths of an inch from the terminal ligature. This ligature must have been placed very close to the origin of the thyroid axis and internal mammary, and the axial rotation, to which the main trunk was subjected, must have had some effect in occluding the origin of these vessels. It is possible, also, that by adopting this radical procedure much interference was caused with the collateral supply furnished by these important branches, as I can account in no other way for the sloughing of the hand and arm which followed. I was, however, so profoundly impressed at the time with the enormous force of the collateral circulation through the vertebral and internal mammary that I would take no chances of secondary hemorrhage by leaving a single ligature at the terminal and injured part of the artery. In fact, I would have ligated the vertebral if the condition of the patient would have permitted of longer delay. After these ligatures had been applied and the vessel thoroughly secured, the traction loop on the mediastinal portion of the subclavian was removed.

The subclavian vein, which had now been detached from the mass of exudates which bound it to the anterior scalene and the arterial opening of communication, was carefully examined. It was found to be circular and to involve only a part of the lumen of the vessel. We therefore proceeded to suture this orifice, and closed it completely without occluding the lumen of the vein. After this had been done the clamp and provisional ligature placed on each side of the sutured point were removed, and it was noticed that the circulation in the vein was restored, though the caliber of the vessel was very much reduced in size, the return flow from the axillary side being very small on account of the great diminution in the arterial supply of the arm.

The subclavian and jugular veins, which previously had been enormously distended, now became very flat and much reduced in size, and presented a very marked contrast to the conditions existing prior to the ligation of the artery.

The patient's condition had, in the meantime, undergone serious and unfavorable changes during these long, tedious, and exhausting manipulations. The pulse at 11:16 was 100, at 12, it was 120; and at 12:20, when the first great gush of blood followed the detachment of the vein, it rose immediately to 140. The quality of the pulse, which had been remarkably good before, now showed the marked effects of shock, though it remained fairly good. Nevertheless, we decided to infuse with saline solution, and four and a half pints of hot salt solution—0.5 of 1 per cent—were injected through the median basilic, which had been exposed and held in readiness for the purpose. This brought down the pulse to 108; but it again grew weak, and at 2 p. m. was 140 again. In the meantime the patient, who was very pale and covered with a profuse cold sweat, was made to drink freely of toddy and given hypodermics of strychnin and digitalin, with 0.01 gr. of atropia sulph.

*Seventh Stage. Readjustment of flap; closure of wound; drainage.* While these restorative measures were being vigorously applied we attempted to replace the clavicle with the osteoplastic flap—skin, aponeurosis, sternomastoid—into position, but found that by so doing it would be difficult to obtain a complete apposition of the soft parts above the clavicle, and thus leave dead spaces. I therefore decided to sacrifice the bone for the sake of obliterating all dead spaces, and removed it entirely from the musculocutaneous flap, to which it was firmly attached by its periosteal covering. An iodoform gauze drain was left in the anterior mediastinum, and the flap was sutured into place by a series of interrupted silkworm sutures.

*Eighth Stage.* The bullet was extracted by an incision over the anterior edge of the trapezius, and found to be a 38-caliber and absolutely undeformed. It had not even grazed the clavicle, as I at first suspected, and had passed upward under the bone without touching it. This remarkable fact could only be accounted for by the elevation of the arm when the patient was shot, and while he was holding his antagonist to the ground.

A large, firm, dry gauze compress was now applied over the field of the operation, reinforced with an absorbent cotton pad, all being held by a long spica, which equally compressed the wounded surfaces. In addition, large broad strips of adhesive plaster were applied over the bandage and over the shoulder, from the scapular region to the chest, thus giving additional security to the bandage. The arm, which was quite cold on the affected side, was now wrapped up in cotton batting from the fingers to the axilla, the cotton being held in place by a loose, spiral roller bandage.

The patient was perfectly conscious, but completely exhausted and shocked. He was extremely pale, the pupils moderately dilated, and the pulse small, and for a few moments after he had been transferred to the rolling carriage it was very small and scarcely perceptible at the wrist. He complained of chilly sensations and shivered. After warming him with hot bags and blankets he was, at 2:15 p. m., taken to his bed, when he was given a toddy and copious draughts of ice water, which he craved incessantly, and which fortunately he never rejected. At 3:45 p. m. he was still extremely

weak, almost collapsed; he felt cold on the surface, but the thermometer in the rectum showed a temperature of 103.6. At 1:50 p. m. the rectal temperature was 104, and half an hour later 104.2. At 10 p. m. his pulse, which at one time had risen to 150, had fallen to 100, beating regularly, full, and strong; his temperature had fallen to 101.6, and he was resting quietly, but perspiring profusely as defervescence progressed.

(To be continued.)

## The Organization of the Medical Profession.

(Continued from p. 113.)

### II.

#### OBJECTS OF ORGANIZATION.

Last week we quoted the objects of organization as given in the constitution of the American Medical Association. The paragraph analyzed gives the following: 1, to foster the growth and diffusion of medical knowledge—educational; 2, to promote friendly intercourse among physicians—social; 3, to safeguard the material interests of the profession; 4, to elevate the standard of medical education; 5, to secure and enforce medical laws; 6, to enlighten the public in regard to hygiene and preventive medicine; 7, to compel recognition by the laity of what our profession has done for humanity. Simply a statement of the above as the basis of organization ought to be sufficient to convince any physician of his duty, namely, to assist in every way possible in furthering these objects.

*Scientific and Educational.*—The noblest and most worthy object for which a medical society is organized is the education of its members in that which relates to their work. There is no other calling in which it is so necessary to constantly study as in that of medicine. Medicine is not an exact, but a progressive science, and until perfection is obtained and all of Nature's secrets are learned, it will continue a progressive one. Theory alone governed the medical men of old even as regards the gross structure of the human body. Until 1543, when Andreas Vesalius published his "*Fabrica Humani Corporis*" there were practically no facts for the foundation of medical practice, and it was almost centuries before the facts that Vesalius gave us were appreciated. The physiology of breathing was a foolish theory until Mayow, in 1668, discovered a partial fact in his *igneo-aereal* substance, but it took a hundred years for a Priestley to discover the whole of that fact and name it oxygen. Facts took the place of theory very slowly until the last fifty years, and even until the last thirty years. But now facts are rushing upon us so rapidly that theory in every branch of medicine is tottering. Not two decades ago, since possibly a majority of those now practicing graduated, the theory as to the cause of inflammation of the bowels, peritonitis and perityphlitis has been supplanted by the fact of an inflamed vermiform appendix; and the fact that an insect causes the spread of malarial fever, yellow fever, and possibly other diseases, is taking the place of various theories. Never in the history of medicine has there been such rapid supplantation of theory by facts as is now taking place. So that the man who starts out from a medical college with his degree is laboring

under a most serious mistake if he thinks that he is educated. For even if he has mastered the medical knowledge of the day, which is improbable, he has entered a profession that is moving forward, and if he would be among the first he must associate with those in the front and be spurred on by their enthusiasm and by their assistance. He who does not is bound to be left behind. The knowledge of what is going on in regard to medical progress can be learned from medical journals, but with difficulty. It may be stated that a very few do keep in touch with this progress by reading only; the progressive men belong to medical societies. Progress is not made by jumps and bounds. "What we know and what we think is not a new fountain gushing forth from the barren rock of the unknown at the stroke of the rod of our own intellect. It is a stream which flows by us and through us, fed by the far off rivulets of long ago." (Foster.) The ebb and flow of this stream is reflected first in our medical societies, and then, but with less interest, in our scientific journals. In the former every statement is examined, criticised, proven false or true by the reasoning together of those competent to judge. In the latter, the same statement appears cold and is to be analyzed by the individual reader by himself alone.

The meeting together in medical societies makes physicians broad-minded and liberal toward the views of others. It makes the average individual recognize his own shortcomings and the abilities of others. It stimulates study and investigation, for the greatest stimulus to study and investigation comes from association with students and investigators. The competition of trade urges the merchant to greater enterprises, and seeing his fellow-laborer at work nerves the toiler's arm. The stimulus of association with the workers nerves those with ambition to keep up with the leaders.

The physician, especially the general practitioner in the country, works under peculiar and in some respects unfortunate conditions—he works alone. Men in other callings either work or meet together with others to exchange views regarding their labors. Even the farmer, following the plow from morning until night, manages to meet his neighbors at the store or elsewhere and discusses with them the crop conditions and prospects, and exchange experiences. A lonely worker in any calling is liable to become self-reliant in what he does—too much so for his own good, as well as for the good of those who use his services. If the work is one of the handicrafts in which manual dexterity is the all-important, it does not matter so much. Practice in this makes perfect. But the work of the physician is peculiar in that practice does not make to perfection. His is a progressive work, and if he does not progress he is left behind.

The physician who works alone day after day without associating with his fellows in like work will, in spite of himself, become narrow, get into a rut, and his professional horizon will soon extend only to the narrowed confines of his own narrowed views and medical life. The tendency of his work is to make him morbid; he is convinced that he is doing his work better than others. He is not stimulated with the ambition to progress because he does not know, will not believe, that others

are progressing. Nothing will prevent this deplorable condition so well as an occasional attendance at a society meeting where physicians gather to discuss scientific questions that vitally affect them and their work. He who does this will be kept out of the rut; his self-conceit will be modified at least, and a realization of the fact that others know as much as he, will compel him to render that respect which is their due.

The medical society is a postgraduate school at one's door, to which the members can, with the mutual help of each other, continue the education which was simply begun in the medical college; it is an institution that the physician will encourage and utilize if he is ambitious to be in touch with the progress that his profession is making.

We propose later to refer to the subject of the medical society as a scientific and educational body, for the purpose of considering the advisability of adopting methods of conducting the scientific work different from that which now prevails.

*Social.*—The second object of organization is the promotion of friendly intercourse among physicians. One of the greatest curses of our profession is the existence of petty jealousies that seem to be so prevalent. It will not be well at this time to consider in detail why these jealousies exist, suffice to say that as a general proposition it can be summed up in the word "misunderstanding." That the isolated character of our work is the primary cause there is little doubt. Too often enmity is created between two physicians living in the same neighborhood through the silly tattle of vamping idlers. Prejudices founded on imaginary insults or wrongs are allowed to grow into deadly animosities. One of the best preventives, as well as the best remedy, is the coming together of the supposed enemies and face to face talk it over. Few of us are as black as our enemies think. A closer acquaintance will reveal lots of good that could not be detected at a distance. An active local medical society is a splendid preventive of local jealousies, especially if a little time be given for sociability and for fraternizing, and if to this be added an occasional luncheon or dinner, the results in this regard will be surprising. Crossing legs under the same table, eating salt from the same salt-cellar, and breaking bread together will banish petty animosities as the noonday sun banishes the mist of the morning. If the medical society had no other value than that of a social club for medical men, it would be worth all it costs.

(To be continued.)

---

**Simplified Technique for Staining the Gonococcus.**—Antoni claims that the following technique differentiates the gonococcus in a few minutes with ease and precision: One of the prepared slides is stained with methylene blue for a minute to obtain a general idea of the field. The others are placed in anilin gentian violet for twenty seconds and rinsed at once. They are then dipped for a minute in the iodo-iodid solution, renewing the fluid several times, then drained without rinsing and alcohol is poured on them, a drop at a time, for two or three minutes. After this they are rinsed and stained with safranin for a minute, renewing the liquid once, and are finally copiously rinsed. All bacteria other than the gonococcus stain blue, while the latter has the color of the safranin. The technique was described more fully in *Hygieu* for February, 1901.

# THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Subscription price: Five dollars per annum in advance

SATURDAY, JANUARY 18, 1902.

## AMERICAN MEDICAL LITERATURE.

The progress that medicine is making in this country is illustrated strikingly by the increasing number of strictly scientific publications of a periodical character as well as by the noteworthy improvement in the reading matter furnished by the weekly and other journals devoted more particularly to the clinical or practical aspects of medicine.

A few years ago the *Journal of Experimental Medicine* began to appear as the first representative of the purely scientific and investigative activities of the laboratories and other institutions doing work of this kind. Upon the title page appeared the names of three associate editors for physiology, but before long the *American Journal of Physiology* was started as the special medium of publication for original investigations in that branch of science. Less than a year ago the *Journal of Medical Research* was founded in response to an urgent demand of the American Association of Pathologists and Bacteriologists for a medium of publication of the papers presented at its meetings. Still more recently the *American Journal of Anatomy* appeared for the purpose of collecting in one place and presenting in a worthy manner the researches of the American investigators in anatomy and allied branches. The material and the style of these publications compare favorably with those of other and older countries. These journals have high standards; there appears to be no lack of proper material to fill their pages; and although they are expensive publications the necessary funds seem to be at hand. Modern scientific medicine in America has certainly profited much and will continue to be greatly advanced by journals of such high character in subjects of fundamental importance. Only by such means is it possible for purely scientific investigation to receive the proper recognition and stimulation, at home as well as abroad.

As regards the periodicals that appeal more directly to the practitioner there undoubtedly has been much advance in the quality of recent years when the greatly increased quantity of material presented is considered. In other words there is a much larger amount of good medical literature of clinical character published in this country now than formerly, and it is not the intention to infer that the best American clinical literature for a long period of time has not been fully abreast with similar kind of literature elsewhere. The increased

amount of creditable current literature means that the general medical profession has higher standards for such work. Still the large part of current medical literature of our country devoted to the solution of such questions as "what is good for biliousness, or low fever, or pneumonia," serves to indicate the general trend of medical thought of a fairly large share of our profession, and unfortunately it must serve also as an index of its scientific standard. This sort of literature is even yet far from being extinct, but the increasing quantity of good literature shows the direction in which development is going.

## THE WHITENING OF THE HAIR.

Metchnikoff, the great champion of phagocytosis, has begun to study the development of senile atrophy from a biologic standpoint. Because senility so often manifests itself at a time in the life of the individual when the instinct of self-preservation is pronounced, and because the wearing out of the body and spirit is not always accompanied by the feeling of need of repose, Metchnikoff suggests that much of the senility of the present day is abnormal and that it might be possible to discover remedies for it.

In order to make a start in his biologic studies of senility he has recently investigated the mechanism of the whitening of the hair,<sup>1</sup> a phenomenon commonly regarded as the most frequent early sign of approaching senility. In certain of its aspects, at least, the change of color of the hair would seem to be within easy reach of investigation. It has been shown conclusively that old hair may turn gray and white; that white hairs are not necessarily white from the start. Metchnikoff at once asks whether the theory of phagocytosis may not throw some light upon the disappearance of the pigment. He finds that hairs of dogs which are turning white contain pigmented cells with well-marked protoplasmic prolongations. These cells are loaded with pigment which they appear to remove from the hairs, beginning first in the peripheral layer. Hence Metchnikoff terms them "pigmentophages." He believes that they come from the medullary layer of the hair, in other words that they are of epidermal origin. In dogs he has traced the pigmentophage cells into the root of the hair and the neighboring tissue. The same or exactly similar cells are present also in human hair that is losing its pigment. The cells may descend to the root of the hair and enter the adjacent tissue or it is also likely that some of them pass to the surface of the hairs and are lost. Metchnikoff does not believe that the entrance of air into the hairs has anything to do with the whitening, which depends on actual loss of pigment. The mechanism is the same in precocious as in senile canities. How are we to explain the undoubted examples of hair "turning gray or white in a night," that is, very rapidly? Metchnikoff suggests that it is due to exceptionally strong stimulation of pigmentophage cells by violent

1. Ann. de l'Institut Pasteur, 1901, xv, 865-879.

emotions, which we know in some way exercise undoubted influence upon vital functions.

While the mechanism of depigmentation described by Metchnikoff seems to be well worked out he has not yet been able to reach any good explanation of the causes that start it to operate. He suggests that when the hair turns gray during infectious diseases, *e. g.*, typhoid, toxic substances stimulate the pigmentophages into activity. In the case of senile whitening the determining factors seem more obscure and farther removed from our grasp at the present time. Are there any means of hindering the hair from turning gray? The only encouragement that can be given is that the hair and other adnexa of the skin are accessible to chemical and physical agents and that it is possible that such agents may be found which will destroy the pigmentophages and thus stop the destruction of the pigment of our hairs.

#### PHTHISIOPHOBIA.

THE JOURNAL has always opposed the exaggerated estimates of the dangerous communicability of tuberculosis and especially such panicky legislation or regulations as would needlessly increase the hardships of its victims. What has been foreseen and deprecated has come to pass; the agitation and persistent reiteration of its contagiousness have had their effect in the recent ruling of the Treasury Department excluding consumptives, and such regulations as those just enacted in certain New York towns where to entertain a consumptive guest is made a finable misdemeanor. This phthisiophobia, as it has been designated by Knopf, seems to be spreading, and he relates instances of gross inhumanity due to the abject cowardice that has been so largely induced among the laity by the inconsiderate exaggerations of medical writers, who too often in their zeal have let their words overstate the facts. Consumption is not a virulently contagious or infectious disease and we should correct the popular impression that it is. The most that we can say on respectable authority is that it is a communicable one, that if due precautions are not observed there is a danger of introduction into the organism of tubercle germs. This accident, however, is by no means a fatal one, or, as things have been in the past, few if any of us would have ever had a chance to die of anything else.

Too little is being made of the hereditary element: the possibility of this has largely been lost sight of in the general magnification of the transmission ideas. What the public should be taught is that there is comparatively little peril for one not specially predisposed, in occasional contact with a consumptive, and no grounds whatever for any panicky fear of such contact; that a very large proportion of us have harbored the tubercle bacilli and that they have done us no serious harm; that consumption is on the decrease in this and other countries where sanitation has improved and the standard of living is high, and that light and ventilation are the tubercle germ's deadliest foes and its universally be-

stowed disinfectant. It is only avoidable neglect that makes the presence of consumptives in any way dangerous to a community, and it is a reflection on our civilization and on our intelligence that such rules are enacted as those reported from Liberty, New York. Their efficiency is, at best, dubious. Nothing short of a universal tuberculin test, more reliable than any now known, could guard against the pervasive tubercle germ. The present tendency to silly panic over the dangers of consumption will, of course, have its brief day; it will die out as it did nearly a century ago in Southern Europe where its uselessness was demonstrated, but in the meantime it has added to the sum of needless human misery.

The medical profession is largely responsible for its existence and should now do all it can to end it, not in neglecting reasonable measures of precaution, but in counteracting the unreasonable apprehensions of the laity which has been unwittingly aroused.

#### ANGIONEUROTIC EDEMA.

The more or less sudden appearance of edematous swellings in various parts, most frequently in the subcutaneous tissue, in persons with "nervous" tendencies, has led to the establishment of angioneurotic edema. As indicated by the name it is thought that the underlying condition is some form of disturbance in the innervation of the blood vessels. Kohn<sup>1</sup> reports a case and reviews the literature. In Kohn's case the dipping of the hands in hot water brought on the edema; in previous cases the influence of cold in bringing on the circumscribed edematous swellings has been noted. Alcohol, trauma and malaria have also been regarded as of etiologic importance. In not a few cases the disease has manifested a distinct tendency to appear in families, affecting various members and generations of the same family. Associated pathologic conditions are usually not apparent, the swellings being recurrent and transitory. As indicated, they usually involve the subcutaneous tissue, but they may appear in various parts of the body, including important internal organs and the joints.

The exact nature and cause of the neurosis which is held to be the underlying factor can not be stated in definite terms. Reflex irritations in persons with neuropathic tendencies are thought to excite vaso-dilator nerves and thus cause congestion and increased vascular permeability followed by an outpouring of serum. Certainly this statement leaves much to be explained, because it really explains but little. In the first place, what is the actual condition in the many states that we have to be satisfied with designating as neurotic or neuropathic? The answer to this difficult question must needs await a much more satisfactory knowledge of the physics and chemistry of the physiology of nerve action than we now possess. In the next place it should be remembered that it has not been proved that stimulation of the vaso-dilator nerves

1. American Medicine, Dec. 21, 1901.

causes an increased permeability of the vessel walls, plausible as this assumed effect may appear. At all events increased permeability of the vascular wall can not be urged in explanation of the disappearance of the edema, which may be quite as rapid as its appearance.

It would seem as if the transitory accumulations of fluid would be more easily explained as the result of sudden changes in the osmotic equilibrium in the tissues. It is plain that the slightest effort to get at the real nature of phenomena of this kind on the basis of existing knowledge merely result in more or less vague theorizations. The very terms employed serve only to cover our ignorance. The therapy so far, hit upon in the blind gropings of pure empiricism, has proved utterly unavailing.

#### ETIOLOGY OF CANCER

The theories of the cause of cancer are multiplying and each one is novel in its way. One of the latest is that of Dr. James Braithwaite,<sup>1</sup> who recognizes that four chief factors enter into cancer production, viz., over-nutrition, non-oxidation of ingested food, local irritations, and excess of salt in the diet. This last he considers the most important and always present, though it requires the coöperation of at least one, and probably two, of the other factors to make it efficient. The suggestion of the importance of salt as a factor came to him from noticing the infrequency of uterine cancer among Jewesses, whose religion excludes salt pork from their diet. Other considerations in favor of this view in his estimation are the absence of HCl in the vomit of gastric cancer; the fact that salt is a most powerful stimulant to all metabolism; the local prevalence of cancer in certain districts and among certain populations where salt is a specially important element in the diet, together with an excess of nitrogenous food etc. "Cancer houses are," he says, "probably merely houses where there is accommodation to keep a pig and where the diet consists of a good deal of bacon; or where a good deal of butcher's meat is consumed, and with it, of course, salt; or where the inhabitants are old, but their appetites are still good; or when they are women and live well, but lead indoor lives so that the food is not well oxidized." He believes that with the increase of cancer reported of late years it will be found that there has also been a great increase in the consumption of salt. It will be seen that his theory is largely based on assumptions, but the same is true of many others so that it is perhaps not the less entitled to a respectful reception. It will aid in the stimulation of medical thought on the subject and it may be with this multiplication of views and their discussion and rejection we will by a process of exclusion narrow the field of research and come nearer to the truth. In this way each suggestion like the above has its value.

#### KOCH'S CHANGE OF VIEWS.

One of Pasteur's principles was never to state or publish as a definite scientific fact any proposition not absolutely proven. Such a principle is worthy of adoption by all, but especially by those who assume to be, or are

recognized as, authorities on some particular subject. In his address before the London Congress on Tuberculosis, Prof. Koch took exactly opposite views as regards transmissibility of bovine tuberculosis to man from what he was supposed to have held previously. This supposition he claimed was not true and said: "Even in my first circumstantial publication on the etiology of tuberculosis I expressed myself regarding the identity of human tuberculosis and bovine tuberculosis with reserve. Proved facts, which would have enabled me to sharply distinguish these two forms of the disease, were not then at my disposal, but sure proofs of their absolute identity were equally undiscoverable, and I therefore had to leave this question undecided." Dr. Alfred Hillier in the *British Medical Journal*<sup>2</sup> calls attention to the conflict of this statement with one made in Koch's original essay which, as Hillier says, will forever rank as a classic in the history of science. The following extract from that essay is quoted to show that at the time it was written Koch held decided views on this now vexed question:

But the perfect identity and unity of the tuberculous process in different kinds of animals *can not be doubted when attention is diverted from the macroscopic condition of tuberculous organs and from the secondary changes in them, as caseation and calcification, to the primary structure of tubercle, which, as we have already seen, recurs with typical regularity in all the different processes in man, and such is the case also in the apparently widely different forms of tuberculosis in the various species of animals.*

In another portion of his original essay Koch says: "It is certain that the milk of tuberculous animals may give rise to infection." Hillier, commenting on these quotations, says that the original views are "unreservedly" and "decidedly" in conflict with those expressed in London last July, and so it would seem to the casual observer.

#### THE JARGON OF EDDYISM ET ID GENUS OMNE.

An imaginative English writer, in his latest publication, which is a sort of tentative prophecy of what society and the rest of the world are coming to in future years, suggests the possibility that a refined and scented Obeah worship will be in vogue in fashionable society and imagines a witch dance and doctor with feathers and all, as a feature of a future social function in Park Lane. With modern Eddyism in existence and thriving on both sides of the Atlantic the suggestion is not so wild as it seems and may be nearer fulfilment than many of his other vaticinations. We ought to be able to count on the counteracting influence of our profession to some extent, but human nature is a peculiar thing and facts sometimes play strange tricks. For example, it is a curious thing to see a physician—an emeritus professor of Columbia University—posing as a Svengali and claiming to have inspired an actress to achievements far beyond her unaided ability so that under his hypnotic guidance she became an actual Trilby in real life. If the newspapers correctly report him, he believes that he gives out a "spiritual energy" which "materializes" in the activities of the subject. Mind communicates with mind independently of the senses, and this is not confined to man, but occurs also in the lower animals.

1. JOURNAL A. M. A., July 27, 1901, p. 261.

2. Dec. 21, 1901, p. 1843.

1. London Lancet, December 7, 1901.

As an instance of this is cited the recent appearance of cougars and lynxes in Austin Corbin's game preserves in New Hampshire. The deer and elk there somehow managed to communicate the fact of their presence (and desire to be eaten) to these carnivorous cats who had for a century been unknown in that region. The doctor also speaks of "intervening intelligences," "hostile influences," etc., and in short uses much of the jargon of the ghost-raisers that have thrived on the credulity of the public for all time past. We need not credit him with dishonesty in the matter, but as a presumably scientifically educated physician he is a sort of phenomenon. Eddyism is only a sort of "refined and scented" voodooism, and these claims of giving out "energy" and influencing subjects for good or bad are little better.

#### APPENDICITIS AND INFECTIOUS DISEASES.

The pre-eminently local character of appendicitis and its successful surgical treatment have undoubtedly served to distract the attention from its possible relations to infectious diseases in general. In the large majority of the cases local conditions appear to explain satisfactorily the development of appendicitis and its consequences, but there are also forms of appendicitis in which the etiology is not quite so simple, and it is to these forms that Finney and Hamburger<sup>1</sup> direct attention. "Propagated appendicitis" is the term applied by M. Reclus to appendicitis developing from extension of enterocolitis. The nature of the appendix favors stagnation and increased bacterial virulence, which result in greater intensity of the resulting lesions of this part of the intestine. Then there are cases in which appendicitis seems to be a "local expression of a general infection." Finney and Hamburger cite three cases associated with rheumatic polyarthritis, and they also refer to similar observations by previous writers not only in the case of rheumatic polyarthritis but also in other infectious diseases, such as measles, typhoid fever, scarlet fever, influenza, etc. Experiments by Adrian and others indicate that the lymphoid tissues of the appendix favor the arrest and growth of bacteria circulating in the blood, because the lesions become manifest here earlier than elsewhere in the intestines. Attention is also called to the apparent relation between influenza and appendicitis, and Adrian has demonstrated the presence of the bacillus of influenza in appendicitis developing in the course of influenza, indicating that the latter disease may stand in direct causal relation to appendicitis. The probable "rheumatic nature" of some cases of appendicitis associated with joint affections is strengthened when one considers the analogy between the tonsils and the appendix, especially in their richness of lymphoid tissue. Bland Sutton has called the appendix "the abdominal tonsil," and as there is a rheumatic tonsillitis why should there not also be a rheumatic appendicitis, using the word rheumatic in its ordinary broad sense. Finney and Hamburger are not willing that these suggestions as to the probable nature of some cases of appendicitis in any way should modify the present views as to its treatment. The peculiar local conditions of the appendix render all inflammations of this little blind tube liable to extension to the general

peritoneum, a menace that by most surgeons and physicians is considered as adequately removed only by surgical treatment.

#### THE SURGICAL TREATMENT OF TUBERCULOSIS OF THE PERITONEUM.

In these days we are accustomed to hear much about the great achievements and the astounding progress made by surgery. Cavity after cavity and region after region have been invaded by the bold surgeon, secure by means of his admirable asepsis from doing direct and immediate harm, until it would seem as if the field of internal medicine was rapidly narrowing to the making of diagnosis and the treatment of general diseases. In this rapid expansion of surgery, to use this phrase, no one will deny that there is much actual and permanent progress. It seems to be true, however, that in some instances surgery in its extraordinarily rapid advancement has entered territories which it may be forced to abandon again after a relatively brief period of occupation. The pendulum has been carried too far and the backward movement may be noticeable at least in certain phases of surgical activity. The surgical treatment of tuberculous peritonitis might be cited as a good illustration of the point at issue. In his recent review of the treatment of peritoneal tuberculosis, Fenger,<sup>1</sup> after having carefully reviewed the subject in the light of recent experience that has accumulated from various sources, states: "After having ploughed through this chaos, out of which it is next to impossible to extricate a ray of light, because reasoning is at a standstill despite the enormous labor of a multitude of able and indefatigable workers in all countries, one can not but feel inclined to look for a new departure. It is refreshing at last to find an author (Borchgrevink) who, after the most careful and painstaking labor with all the weapons of modern scientific investigation at his disposal, has the courage to tear down this whole artificial house of cards and make *tabula rasa* of the whole question." Borchgrevink has made a most careful analysis of two almost equal series of cases of peritoneal tuberculosis, one treated by laparotomy (22 cases), and one (18 cases) treated without laparotomy. Without going into details, suffice it to say that the forms of peritoneal tuberculosis without fever or with only slight fever usually run a favorable course and laparotomy is unnecessary, while in progressive tuberculosis most of the patients die from the disease sooner or later, and therefore laparotomy has no influence upon them. As Fenger puts it, nature cures tuberculosis of the peritoneum better than the surgeon. Borchgrevink states that even the "serous tuberculous peritonitis is a territory which surgery must hand back to the internal medicine clinic with thanks for the splendid opportunity which a misunderstanding gave to the profession, by means of laparotomy, to study tuberculosis in one of the large cavities of the body." When able and careful surgeons reach conclusions such as these we may begin to look for a period of greater conservatism in the treatment of peritoneal tuberculosis.

## Medical News.

### CALIFORNIA.

**Smallpox.** The disease is epidemic at Randsburg, where there are about 45 cases. Stockton has several cases. At Los Angeles two new cases have occurred.

**Los Angeles Mortality.** The death rate for Los Angeles in 1891 was 16.58 per 1000. The total number of deaths was 1927, 1168 being males and 759 females. Consumption caused 348 deaths, 298 of the deceased were not natives of California, and of these 255 had lived less than ten years in the state.

**New Pasadena Hospital.** The new hospital, which has been given to Pasadena by a number of philanthropists, was formally opened January 5. The ceremonies partook of the nature of a donation party, and about \$1400 in cash and quantities of supplies were presented by friends of the institution.

**Personal.** Dr. Henry T. Woodward returned to San Diego, December 24, after a residence of three years in Europe. Dr. Hugh S. Cummings, U. S. M. H. Service, has succeeded Dr. Duncan A. Carmichael in command of the Angel Island Quarantine. Col. Robert M. O'Reilly succeeded Col. Charles R. Greenleaf as chief surgeon of the Department of California, January 1.

**Doctor Convicted.** It is announced in the *Detroit Free Press* in a special dispatch from La Porte, Ind., that Dr. Amos J. Landis, "who recently went from Adamsville, Mich., to Chico, Cal., has been convicted of forgery and a sentence of seven years in the penitentiary has been imposed. Dr. Landis treated a wealthy bachelor, who left him \$20,000 by executing a note for that amount on his deathbed. The bequest was contested in the courts by the relatives of the dead man and experts for the prosecution claim the note was forged by the physician. The friends of Dr. Landis believe him innocent and a defense fund is being raised by Michigan and Indiana physicians to enable Dr. Landis to carry his case to the higher courts. The man Dr. Landis treated had been abandoned by his relatives despite the fact that he was possessed of a large fortune.

### DISTRICT OF COLUMBIA.

**Health of the District.** The report of the Health Officer for the week ended January 11 shows the total number of deaths to have been 108, of which number 62 were white and 46 colored. The total number of births was 108 at the close of the week. Forty-two cases of scarlet fever and 34 cases of diphtheria were under treatment.

**Health of Working Girls.** The Senate adopted a resolution directing the Committee on the District of Columbia to determine whether the law adopted March, 1895, providing that all persons employing female help in stores, shops or manufactures in the District of Columbia shall provide seats for them when not actually engaged, is being carried out, and if it finds that it is not, to ascertain why its enforcement is neglected. The Committee will report to the Senate at an early date.

**Medical Bills in Congress.** The following bills have been introduced in Congress and are being considered by the Committee of the American Medical Association on National Legislation, consisting of Drs. H. L. E. Johnson, Washington, D. C.; William H. Welch, Baltimore, and W. L. Rodman, Philadelphia:

H. R. Bill 1952, by Mr. Hay, to define the duties of the Medical Department of the Army of the United States:

Be it enacted, etc.,

That the duties of the Medical Department of the Army of the United States shall be as follows:

1. The direction of measures for the prevention of the ingress of disease among the troops of the Army and of sanitary faults in location and construction of posts and camps.

2. The medical and surgical care of diseased and injured officers and soldiers of the Army of the United States; the physical examination of all officers and soldiers entering or leaving the Army of the United States.

3. The care of and accountability for all transportation pertaining to the movement of men and supplies of the Medical Department and of the sick and injured of the Army.

4. The preparation and preservation of the records of transactions taking place under the three preceding paragraphs.

5. It shall be the duty of the senior medical officer of the army corps, division or brigade, territorial division or department, in which an unusual outbreak of disease shall have arisen to at once take steps to investigate and determine the reasons therefor.

Should this investigation show any carelessness or inattention to duty, either upon the part of the medical officer or of the officer in command at the infected point, he shall at once make a report to the general officer in command of the facts, whose duty it shall then become to bring the offending officer or officers before a court-martial for such punishment as upon conviction, the court may deem proper and the reviewing authority concur in.

6. The Medical Department shall also perform such other duties as the President or the Secretary of War may deem for the best interest of the Army.

7. The Secretary of War is hereby authorized and directed to prepare suitable regulations for the enforcement of the provisions of this act.

All acts and parts of acts in conflict with the above are hereby repealed.

H. R. Bill 7198, by Mr. Hepburn: To increase the efficiency and change the name of United States Marine Hospital Service. (This bill previously printed in THE JOURNAL.)

H. R. Bill 7650, by Mr. Kern: To reestablish the Army Canteen.

H. R. Bill 7931, by Mr. Jenkins: For the promotion of Anatomical Science, and to prevent the desecration of graves in the District of Columbia.

H. R. Bill 8189, by Mr. Miller: In relation to Pharmacy in the Indian Territory.

H. R. Bill 8194, by Mr. Hull: To equalize the pay of officers of the Line, Medical Corps, Pay and Chaplain Corps of the Navy with officers of corresponding rank in the Army and Marine Corps.

Senate Bill 189, Mr. Gallinger: For the further prevention of cruelty to animals in the District of Columbia. (The revived Anti-vivisection Bill.)

Senate Bill 2472, by Mr. Proctor: To provide for the payment of medical expenses of sick officers and enlisted men of the Army while absent from duty with leave or on furlough.

Senate Bill 2420, by Mr. Hansbrough: For the relief of assistant surgeons in the Volunteer Army of the United States.

Senate Bill 2519, Mr. Pettus: To add dental surgeons to the Medical Corps of the Navy.

### GEORGIA.

**Isolation Hospital Needed.**—Dr. Benjamin W. Bizzell, Atlanta, a member of the Board of Health, is making a determined effort to secure an appropriation of \$5000 for the construction of a contagious disease hospital, the need for which is urgent, as there is no place in the city where patients suffering from communicable diseases can be received and treated.

**Personal.**—Dr. Floyd W. McKee, Atlanta, who has been suffering from blood poisoning, is improving. —Dr. Henry H. Harmon, Dawson, and H. W. Harris, Shellman, have exchanged locations. —Dr. J. W. Lee Brannon, Valdosta, has located in Atlanta, and Dr. D. Q. Dallas, Tallahassee, succeeds him. —Dr. Isham H. Goss, Athens, has been appointed a member of the State Board of Medical Examiners.

**Decision Against Private Sanatoriums.**—In the habeas corpus proceedings in the United States District Court at Macon it has been decided that the section of the Georgia law permitting private sanatoriums to receive patients and hold them at the will of the proprietor, without the consent of the patient, is in violation of the fourteenth amendment, United States constitution, and therefore null and void.

### ILLINOIS.

**Hospital Site Bought.**—The Kewanee Hospital Association has purchased a tract of land 175 by 150 feet, for \$2500, on which to erect a hospital.

**Staff Elects Officers.**—At the annual meeting of the staff of St. Mary's Hospital, Quincy, Dr. Grant Irwin was elected president; Dr. John D. Justice, vice-president; Dr. William H. Baker, secretary, and Dr. John A. Koch, treasurer.

**St. Joseph's Hospital, Joliet,** reports that in 1901, 901 patients were treated at the hospital, of whom 57 died. Of these, however, 21 were moribund when brought to the hospital. The Sisters also cared for 252 patients in private families during the year, making a total of 1153. Dr. A. J. Lennon has been added to the medical staff.

**Personal.**—Dr. Henry Richings, Rockford, has been appointed a member of the State Board of Health. —Dr. W. C. Phipps has located in St. Augustine. —Dr. William Friend, Lancaster, has located in Sumner. —Dr. Clarence A. Wells retired from the position of assistant surgeon at the Soldiers' Home Hospital, Quincy, December 31. —Dr. William A. Gray, Milledgeville, has located in Freeport. —Dr. Justin C. Simpkins, Danville, has moved to Granville, N. Dak. —Dr. George A. Zeller, Peoria, recently appointed superintendent of the State Hospital for the Incurable Insane, near Peoria, is on his way from the Philippines to his post of duty.

### Chicago.

**Visiting Nurses.**—The Visiting Nurses' Association, at its annual meeting, reported a most successful year. Nurses were provided without charge in 5915 cases, and 37,556 visits were made.

**The Chicago Polyclinic and Hospital** has purchased the southeast corner of LaSalle Avenue and Oak Street. The plot of land has a frontage of 150 feet on LaSalle Avenue and 120 feet on Oak Street.

**Woman's Medical College Sold.**—The Northwestern University Woman's Medical School building has been sold to the

Chicago Eclectic Medical College and the Valparaiso, Ind., Normal School, for \$40,000.

**The Chicago Lying-in Hospital Dispensary** finished last week 2000 consecutive confinement cases without a maternal death. In 3763 consecutive labor cases, under the exclusive care of the dispensary, two died, both from spontaneous rupture of the uterus. In all these cases there were only 8 septic fever cases that were at all sick. In two the uterus was cleaned out, in none was any other local treatment instituted. The number of directors has been decreased from eleven to nine.

**The Week's Mortality.**—For the week ended January 11, the mortality per 1000 was at the annual rate of 14.78; for the corresponding week of 1901, the figures were 16.34. The Department of Health reports a reduction of 67 per cent. in the deaths of those more than 60 years of age as compared with the same week of last year. The deaths from pneumonia and influenza show a marked comparative decrease, the respective proportions being 89 to 161 and 4 to 18. The department denies the report now current that erysipelas is raging in the city. In the last two weeks there have been only four deaths from the disease.

#### INDIANA.

**State Medical Board.**—At its meeting December 10, the Board refused recognition to the Curtis Physio-Medical Institute, Marion, revoked the license of Harry S. Kiskadden, Huntington, and continued the case of J. P. Shepherd, Judson, charged with falsely obtaining a certificate of license from the Board and selling it to Albert E. Kirk, a veterinarian.

**Indianapolis Coroner's Year.**—During the year, Coroner Dr. Alembert W. Brayton reports that he investigated 309 deaths, 226 males and 83 females. Of these 35 were railroad cases. Suicide caused 29 deaths, of which 8 were from morphin; 3, carbolic acid; 1, cocaine; 3, arsenic; 4, gunshot wounds; 4, hanging; 2, drowning; 1, chloroform, and 1, asphyxiation by gas.

**Personal.**—Dr. Davis W. Tucker, Boonville, has moved to Fort Wayne.—Dr. J. J. Graham, Daleville, has located three miles south of Paoli.—Dr. Frederick W. Denke-Walter, Spencer, has sold his sanatorium and moved to McCormick's Creek.—Dr. Frank Broughton, Waterloo, has been appointed local surgeon of the Lake Shore road.—Dr. Royal H. Hardman, Converse, has located in South Bend.—Dr. James Lewis, senior interne at the Indianapolis City Hospital, has resigned and will practice in the city.

#### IOWA.

**To Increase Fees.**—Stout City physicians of both schools to the number of about 90 have agreed to advance professional fees. It is proposed to raise the fee for a visit from \$1.50 to \$2.

**Smallpox.**—Bagley fears an epidemic. Dr. M. C. Hess reports that the disease has appeared in two families and that many have been exposed. Dr. J. A. Pringle reported 3 cases last week, and several families are under quarantine.

**Personal.**—Dr. Wilton W. McCarthy, Des Moines, has been appointed surgeon-general of Iowa, in place of Dr. J. Taggart Priestley.—Dr. William B. Small, Waterloo, has moved to Castalia.—Dr. Norman S. Craig, Manchester, has gone to Jennings, Fla., for the winter.—Dr. Herbert W. Linder, Stratford, has moved to Nevada.—Dr. P. Sherlock, Martinsburg, has purchased property near La Plata, Mo., and will move there in March.—Dr. Henry E. Douglass, Independence, has located in Jesup.—Dr. Elmer E. Bamford, Allerton, has moved to Centerville.—Dr. Frank F. Winsell, Drakesville, has located in Bloomfield.—Dr. Gysbert P. Van Marel, Oto, has opened an office in Pella.—Dr. Oren T. Wertz, Dixon, has moved to Morley.—Dr. A. R. Rogers, Minburn, has purchased the property of Dr. John B. Conly, Woodward, and will practice there.—Dr. A. John Droz, West Chester, will locate in Keota, this month.

#### MARYLAND.

**Baltimore's Mortality.**—The mortality for the week ending January 11, was 205; white 167, colored 38. Pneumonia caused 26 deaths, consumption 17 and cancer 7.

**Registration of Pharmacists.**—A bill for the registration of all pharmacists in the state has been introduced in the Maryland Legislature. It is identical with the bill of 1900, with a few exceptions. One change is in allowing ordinary stores to sell drugs and medicines, but not to put up prescriptions.

tions. This is a concession to the wholesale trade, which it is said is now a unit for the bill.

**Personal.**—Dr. James M. Spear has been appointed physician to the Allegheny County almshouse and jail and secretary of the County Board of Health.—Dr. William F. Twigg has been appointed physician to the insane asylum.—Assistant Surgeon F. C. McDonald, U. S. Navy, has relieved Assistant Surgeon A. M. Fauntleroy at the United States Naval Academy, Annapolis, the latter being ordered to the Naval Hospital at Norfolk, Va.

**Insane Hospital Report.**—At the close of the last fiscal year of the Springfield Hospital for the Insane there were 330 inmates; 234 males and 962 females. During the year 22 died, 14 were discharged recovered, 8 discharged improved, and 3 discharged unimproved. Dr. J. C. Clarke says no general feature of treatment is more important than properly selected work. The patients do a large amount of outdoor work, and among them are carpenters, painters, stonemasons, bricklayers, tailors, shoemakers, etc., who work at their trades daily and seem much happier in pursuing their accustomed avocations than in sitting idly in the wards.

**Interesting Papers Before Societies.**—Several interesting papers have been brought before the societies here in the past week. Dr. Simon Flexner described his new researches on snake venom, undertaken on the suggestion of Dr. S. Weir Mitchell. He used the venom of the rattlesnake, copperhead and cobra, and finds it to be a complex virus, the two main elements acting on the red blood corpuscles and nerve cells. Dr. William Osler spoke of the cerebral symptoms (coma) associated with latent carcinoma of the stomach. Dr. Charles P. Emerson spoke of digestive processes in carcinoma of the stomach and endeavored to prove that the absence of free hydrochloric acid is brought about by some element or elements in the growth "binding" it or using it up. Dr. John Ruhrah exhibited a meningocele removed from the occiput of an infant aged 17 months. Its size can be judged by the fact that it contained 1½ gallons of fluid. This is the largest meningocele ever reported. The child died in four days. Dr. C. W. Burr, Philadelphia, urged the importance of preparing patients for operations in order to avoid subsequent shock and neurasthenia. This applies to chronic surgical cases, and especially in gynecological practice. Dr. Harvey W. Cushing reported the recent researches of Professor Shearington, of Liverpool, in cerebral localization.

#### MICHIGAN.

**Comparative Prevalence of Disease.**—For the month of December, compared with the preceding month, pleuritis, pneumonia, scarlet fever, inflammation of kidney, smallpox, erysipelas, inflammation of bowels and cerebrospinal meningitis were more prevalent; and intermittent fever, remittent fever, whooping cough and diphtheria were less prevalent. For the same month compared with the average for December in the ten years, 1891-1900, scarlet fever, smallpox, measles and cerebrospinal meningitis were more than usually prevalent; and consumption, intermittent fever, erysipelas, remittent fever and diphtheria were less than usually prevalent.

**The Most Dangerous Communicable Diseases.**—Including reports by regular observers and others, cerebrospinal meningitis was reported during December, at 6 places; whooping cough, 32 places; measles, 39 places; diphtheria, 85 places; typhoid fever, 109 places; smallpox, 141 places; scarlet fever, 184 places, and consumption, 204 places. Reports from all sources show cerebrospinal meningitis reported at 5 places more; whooping cough, 1 place less; measles, 12 places more; diphtheria, 11 places less; typhoid fever, 57 places less; smallpox, 49 places more; scarlet fever, 2 places more, and consumption, 6 places more, in December than in the preceding month.

**Mortality in Michigan During December.**—The month of December was a record-breaker as regards prompt reports from local registrars to the secretary of state, over 99.74 per cent. of the population being promptly reported. This is the best record ever made in this country from a state area. There were 2770 deaths returned, corresponding to a death rate of 13.5 per 100,000 population. This number is an increase of 316 over the previous month, but is only 95 more than the number returned for December, 1900. Important causes of deaths were as follows: Pneumonia, 330; influenza, 43; pulmonary tuberculosis, 151; cancer, 126; other forms of tuberculosis, 18; typhoid fever, 53; diphtheria and croup, 54; scarlet fever, 39; measles, 14; whooping cough, 13; accidents and violence, 157.

There was considerable increase in the death rate from typhoid fever, and slight amounts of increase from scarlet fever, measles and whooping cough. Pneumonia and influenza showed a marked increase, as is usual at this season. There were 3 deaths from smallpox during the month, one in Delta and two in Isabella County.

### MISSOURI.

**Lifts Sanatorium Debt.**—Mr. A. D. Brown has fulfilled his promise made several months ago to give the Missouri Baptist Sanatorium, St. Louis, \$50,000, provided \$25,000 were raised outside. This has been done and the sanatorium in consequence is free from debt and has a handsome surplus.

**The St. Louis Medical Society** bids fair to outdo all previous records during the coming year. At the January election there were over 120 votes cast, and the new officers seem determined to make this year notable for scientific work. Dr. Carson, the new president, will have hearty support.

**State Hospital Appointments.**—At the State Lunatic Asylum No. 1, Fulton, the following appointments have been made: Dr. James W. Smith, Pleasant Hill, superintendent; Drs. William M. Barnes, Clarence; J. Frank Harrison, Martinsburg, and Zachary T. Martin, Lathrop, assistants.

**The Medical Director of the World's Fair** has not yet been chosen, but the consensus of opinion is that Dr. Leonidas H. Laidley, professor of gynecology in the Marion Sims college, will be the man—in fact there is no other candidate. Dr. Luther P. Walbridge will probably be the first assistant.

**Alumni Societies of St. Louis.**—The several alumni medical societies are showing good attendance and excellent work. At the University a symposium is given at each meeting on a selected topic, which plan is followed to some extent by the City Hospital Society. The Academy of Medicine has removed to Jefferson Hall on Grand Avenue.

**Fire at St. Francis' Hospital.**—On the night after Christmas, with the mercury at -13 degrees, a fire started in the basement of St. Francis' hospital, Maryville, which threatened to destroy the whole building. After the removal of 13 patients, and five hours' heroic work on the part of firemen and citizens, the fire was extinguished, the loss being about \$2000.

**Hospital Saturday and Sunday.**—During the year the Hospital Saturday and Sunday Association, St. Louis, has received \$24,796.82, an increase of \$6112.86 over the amount received in 1900. The following allotments were made at the annual meeting: Evangelical Deaconess Hospital, \$486.92; Good Samaritan Hospital, \$1661; Martha Parsons Hospital, \$2441.45; St. Louis Children's Hospital, \$5736.19; St. Louis Mullanphy Hospital, \$1904.46; St. Luke's Hospital, \$1544.86; St. Mary's Infirmary, \$4712.22, and St. Louis Protestant Hospital, \$300.35.

**St. Louis Personals.** Several St. Louis physicians have been unfortunate recently in having been sick or injured, but all are rapidly recovering. —Dr. Robert M. Ross was successfully operated upon for appendicitis. —Dr. W. H. Stauffer has made a good recovery from fractured patella. —Dr. Frank Glasgow, who has been dangerously ill from blood poisoning, is better. —Dr. Greenfield Sluder, who was injured by a transit car, is convalescent. —Dr. John B. Johnson, one of the grand old men of the profession, recently celebrated his golden wedding anniversary. A man of wide acquaintance and large experience, his name has long been a synonym for all that is good and noble among St. Louis physicians.

### NEW YORK.

**Regulation of Bath Houses.**—Mr. Pendry has introduced a bill in the legislature amending the public health law by forbidding the establishment of public bath-houses at a point within 1000 feet of any sewer connection and compelling the owners or lessees to provide separate toilet rooms, which must be kept clean and disinfected.

**To Legalize Osteopathy.**—On January 7, Senator Brackett, of Saratoga County, introduced a bill to legalize the practice of osteopathy. The bill not only legalizes the practice of osteopathy, but provides for the appointment of a State Board of Examiners to pass on the qualifications of all who desire to practice in the new school.

**Tuberculous Cows Discovered.**—It is reported that the Commissioner of Agriculture has discovered a herd of tuberculous cattle near Peekskill, belonging to a dairy which regularly shipped its products to New York City. The present owner of the dairy evidently is an amateur, for in the six months of his ownership he has lost nearly 50 out of a herd of 108 cows, and the carcasses of the animals have been strewn about the farm.

### Buffalo.

**Staff Re-elected.**—The officers of the medical staff of the German Hospital were unanimously chosen for a second term at the annual meeting of the staff held January 9.

**Sisters' Hospital Staff.**—The medical and surgical staff of the Sisters' Hospital held its annual meeting and elected officers for the ensuing year as follows: Dr. Henry C. Buswell, president; Dr. Walter D. Greene, vice president; Dr. Max Keiser, secretary, and Drs. Edward J. Myer, James J. Mooney and Charles S. Jewitt, executive committee.

**Emergency Hospital Open.**—The new Emergency Hospital has opened for the reception of patients, and the following hospital staff has been appointed: Medicine—Drs. John H. Pryor and L. Bradley Dorr; surgery—Drs. Clayton M. Daniels, Vertner Kenerson and Francis J. Carr; ophthalmology—Drs. Homer J. Grant and Benjamin H. Grove; laryngology, rhinology and otology—Drs. W. Scott Rinner and Edgar A. Forsyth; dermatology—Dr. Ernest Wende; genito-urinary diseases—Drs. James A. Gardner and N. W. Wilson; nervous diseases—Dr. William C. Krauss, and internes—Drs. C. W. Southworth, J. H. Dewees and G. McKay Holt.

**Personal.**—Dr. H. R. Gaylord, director of the New York State Cancer Laboratory at Buffalo, has been elected a foreign member of the German Cancer Investigation Committee, of which Prof. Von Leyden, of Berlin, is chairman.—Drs. Edward L. Frost and Jacob M. Krauss were elected postmortem examiners by the Board of Supervisors.—The Board also elected Dr. John S. Howland physician to the penitentiary, and Dr. Frank Brusio physician at the jail.—Dr. DeLancy Rochester has resigned from the attending staff of the Sisters' Hospital, and Dr. Emil S. Tobie has been appointed to the medical service.—Dr. George F. Cott has resigned his position as district city physician, after twelve years' service. The position is under the civil service, and Drs. Norman L. Burnham, Ernest L. Ruffner and Keyes, the latter a woman, are on the eligible list.

### New York City.

**Ward Quarantined.**—The male medical ward of the Roosevelt Hospital, containing 30 patients, will be kept under quarantine for three weeks because one of the patients in the ward was discovered to be suffering from smallpox.

**Ambulance Surgeons Commended.**—So often does the hospital ambulance surgeon come in for abuse in the daily press that it is encouraging to note that, in the recent deplorable railroad wreck in this city in the tunnel, the ambulance surgeons of the various hospitals were highly commended for their very efficient, and almost heroic, efforts in the work of rescue.

**New Hospital Opened.**—The New York Infant Asylum formally opened its new hospital building January 11. The building adjoins the old hospital at 61st Street and Amsterdam Avenue, and the two together will now be able to care for 250 patients. The occasion brought together a number of people prominent in society and identified with charitable work, and addresses were delivered by several well-known gentlemen, including Dr. Stephen Smith, one of the original incorporators.

**Superintendent and Chaplain Dies.**—Rev. Thomas G. Wall, well known to those who have had much to do with the Presbyterian Hospital for the past quarter of a century, fell dead while walking through one of the hospital wards. He was 79 years of age and had been very feeble for some months. At one time he was superintendent of the hospital, but of late years he held the position of chaplain. It is thought that his sudden death was caused by the excitement incident to his being called upon to officiate at the wedding of a man who was very sick in the hospital.

**Medical Defense Plan Praised.**—The recent newspaper account of the plan by which the New York County Medical Association proposes to defend its members against "blackmailing schemes and the efforts of pettifogging lawyers to work up malpractice cases among ignorant and dishonest persons," has caught the eye of some companions in misery in the business world, and has drawn from them words of commendation and encouragement. This was well shown by a communication sent to that Association by the Guardian Savings and Loan Company of New York City. The letter states that those who are engaged in managing institutions, of the class coming within the sphere of action of this company, hail with pleasure this attempt of the medical profession of this city to rid itself of the legal persecutions which have too often been carried on in the name of justice. These institutions, it would seem, are picked out, even as physicians are, as good objects for the schemes of designing and unprincipled persons, and hence the

company already mentioned, speaking from sad experience in such matters, expresses the hope that this important movement will extend throughout the state and country, and wishes god-speed to the New York County Medical Association as the pioneers in this effort.

## PENNSYLVANIA.

### Philadelphia.

**Alumni of the Jefferson Medical College** will confer a favor on the editors of *The Jeffersonian* by sending the names and present addresses of the officers of their respective graduating classes to *The Jeffersonian*, care of the Jefferson Medical College, Philadelphia.

**Private Contagious Disease Hospital.**—Philadelphia is in great need of a hospital where private patients may be treated for contagious diseases. A number of public-spirited persons, including many women, have been working to the end that such a hospital may be built. It is proposed to name it the "McKinley Memorial Hospital."

**Vita-Physician Indicted.**—Victor B. Hall, who calls himself a "vita-physician," at a hearing before a magistrate was bound over to court in \$800 bail. Hall has no license to practice medicine, but had recently attended a woman who died; he was unable to give a death certificate because of lack of legal qualification, and the case was investigated by the coroner at that time.

**Mortality and Morbidity.**—The mortality report for the week ended January 11 shows the number of deaths, from all causes, to be 471. Of these, 42 were from contagious diseases, 15 from smallpox; 131 new cases of smallpox were reported for the week. This is the greatest number occurring within any week since the outbreak of the disease. The epidemic does not, however, approach that of 1871 and 1872, when within the two years there were 16,000 cases and more than 3500 deaths. For nearly two weeks, no new cases have developed in the almshouse. The systematic canvass of the city by a corps of special vaccine physicians is almost completed.

**Award of Gross Prize.**—The Philadelphia Academy of Surgery, as Trustees of the Samuel D. Gross prize of \$1000, for original research in Surgery, have awarded this prize, after six years' interval, to Dr. Robert H. M. Dawbarn, of New York City. The treatise which won the competition was entitled "The Treatment of Certain Malignant Growths by Excision of Both External Carotids." Upon this topic Dr. Dawbarn has worked, as opportunity served, for seven years. The essay when published will contain the histories with pathologist's report in each instance confirming the diagnosis of malignancy and specifying its variety, of forty carotid extirpations by the author himself; and as many additional by about a dozen other surgeons. At least two of these are members of the Philadelphia Academy of Surgery. By the terms of Dr. Gross' bequest, the prize-essay must be published in book form, and a copy thereof deposited in the Samuel D. Gross Library of the Philadelphia Academy of Surgery.

## CANADA.

**Obituary.**—Dr. Fortier, physician of St. Vincent de Paul Penitentiary, province of Quebec, died on the 10th inst., at the age of 69 years.

**Smallpox at Ottawa.**—Since the commencement of the present outbreak of smallpox at Ottawa there have been reported to the Medical Officer of Health, 208 cases. There are at present 72 cases there.

**Trouble in a Hospital.**—The Medical Board of the General Hospital, Kingston, Ont., has requested the resignation of Dr. Grimshaw, one of the house surgeons. Dr. Grimshaw, who has refused to resign, will seek the aid of the courts if he is dismissed.

**Victorian Order of Nurses.**—At the Executive Council meeting of the above Order held at Ottawa on January 9, it was reported that the total receipts to date for the Cottage Hospital's Fund was \$23,000 and the expenditure had been about \$15,000. The general central fund now amounts to \$11,000.

**Ontario Board of Health.**—The regular quarterly meeting of this Board of Health was held during the past week in Toronto. Dr. Bryce, the secretary, reported that since the outbreak of smallpox a year ago there have been 1900 cases of which 750 were in the unorganized districts of Ontario. There have been but twelve deaths, a mortality of only two-thirds of 1 per cent.

**Appointment.**—Dr. A. T. Hobbs, late assistant surgeon of the London Asylum for the Insane, has been appointed superintendent of the "Homewood Retreat," a private hospital at Guelph for victims of dipsomania and morphinism. Dr. Hobbs is well known for his gynecologic surgery on the female insane while interne at the London Asylum.

**New Asylum Opened in Ontario.**—On January 4, the new Asylum for Insane, for female patients alone, was opened at Coburg, Ont., the old buildings of Victoria University having been remodeled for the purpose. This Asylum will have accommodation for 150 patients. Dr. McNichol of Coburg will be the superintendent and he will have associated with him as assistant a female physician, Dr. Cockburn of Toronto.

**Ontario Medical Defense Association.**—A number of practitioners throughout the province of Ontario waited on the Premier last week to request that legislation be introduced at the present session of the Ontario House of Assembly which will make the medical profession in this province self-governing by eliminating from the Medical Council of the College of Physicians and Surgeons the appointed and homeopathic elements. The matter will be considered by the Government.

**Consumption Sanitarium for Calgary, N. W. T.**—The City Council of Calgary recently passed a resolution, copies of which have been sent to Ottawa, protesting against the increased number of consumptives who are sent to the western city on account of the fine climate of that district. Practically all of these come from Ontario and other provinces in the east; and the resolution calls upon the Dominion Government to erect a sanitarium for the care and treatment of consumptives or else grant aid for the purpose. The Calgary Council will gladly coöperate with the Dominion Government in the matter.

**Personals.**—Dr. Peter B. Wood, at one time a famous twirler in the old International Baseball League, and who has been residing and practicing in Butte and Anaconda, Montana, has returned to Canada to practice at Hamilton, Ont.—Dr. E. P. Benoit has been appointed physician to the Montreal jail.—Dr. G. C. Ferrier, who was graduated from Queen's Medical College two years ago, has been appointed a member of the Canadian Field Hospital Corps for service in South Africa. For the completion of this Field Hospital, each of the medical colleges of the Dominion has furnished its quota.

**Toronto Home for Incurables.**—A deputation from the Trustees of this institution recently waited on the Premier of the province with regard to securing an increased government grant. During the twenty-seven years the institution has been in existence it has been doing invaluable work; and during the past ten years the attendance has increased one-third. The Government's grant in 1893, when the attendance was 117, was \$5651, whilst it was only \$3100 in 1899, when the attendance was 132. Last year the grant was \$3300. The accommodation is now taxed to its utmost, and applicants are forced to await their turn.

**Sir William Hingston's Jubilee.**—One evening last week a large number of the friends and confrères of Sir William Hingston, Montreal, waited on him and presented the distinguished surgeon with a portrait of himself in oil. The occasion was the celebration of his professional jubilee, Sir William having been graduated from McGill University in 1851. Sir William Hingston has always been prominently identified with the progress of medicine throughout the Dominion. He organized the first Board of Health in the Dominion, is a past-president of the Canadian Medical Association, is an honorary D.C.L. of Bishop's College University, an honorary LL.D. of Victoria University, Toronto, and is a vice-president of the Montreal Branch of the St. John's Ambulance Association.

## FOREIGN.

**Typhoid Fever in City of Mexico.**—Special efforts are being made by the city government to restrict the spread of typhoid fever, which is quite prevalent at the present time.

**International Congress of Hydrology, Climatology and Geology.**—The sixth international congress will meet at Grenoble, France, in October, 1902. The address on the "Action of Mineral Waters on the Tissues" will be by Renaud of Lyons; "Microbiologic Analysis of Mineral Waters," by Bordes, and on "Climatology" by some of the Paris physicians who have been engaged in the medical balloon ascents. Hydro-mineral treatment of pulmonary phthisis, of cutaneous and gastric affections and also of constitutional taints in children, will be discussed by A. Robin, Carron de la Carrière and others.

**Prizes for Essays on Tuberculosis Sanatorium.**—From the large sum of money placed at the disposal of King Edward

£800 will be awarded as prizes for the best essays on tuberculosis sanatoria. The following are the conditions defined by the Advisory Committee, whose names were given in our last issue:

1 Medical men of all nationalities may compete. The papers may be either the work of a medical man or the joint production of a medical man and an architect.

2 The sanatorium is intended for 100 tuberculous patients, 50 males and 50 females.

3 Of the total number of beds, 88 will be assigned to the more necessitous classes, whilst 12 will be reserved for the well-to-do.

4 The accommodation for all patients is to be comfortable, a separate room being provided for each. Superior arrangements to be made for the more wealthy patients.

5 It may be taken for granted that the sanatorium will be erected on an elevated and sloping site with a sunny exposure, and well sheltered from cold winds. It will have a farm at a convenient distance, and be surrounded by extensive grounds, well wooded, and affording ample space for exercises of various kinds. The soil will be dry and permeable, and the water supply abundant.

6 The sanatorium must be fitted with the latest sanitary arrangements, and equipped with all requirements for scientific research. Provision should also be made for the recreation of the patients.

7 Economy in construction will be an important consideration, but it must not interfere with the reasonable comfort of the patients or the efficiency of the institution.

8 The essays must be in English and type-written.

9 The essays must not bear the name or names of their authors, but should have a motto, and each essay should be accompanied by a sealed envelope bearing the motto on the outside and containing the full name and address of the author or authors inside.

10 All essays and plans must be sent, postage paid, on or before the 15th of April, 1902, to one of the secretaries to the Advisory Committee.

11 Three money prizes of £500, £200, and £100 respectively will be awarded in order of merit on the recommendation of the Advisory Committee for the three best essays, provided they come up to the requisite standard of excellence. Brevity will be an important consideration and a summary of the main features of the scheme should be appended to the paper. Unsuccessful papers will be returned to the authors.

#### LONDON LETTER.

##### The Smallpox Epidemic—Great Increase.

The epidemic of smallpox in London continues to progress. The number of cases in hospital now amount to 739, and 24 have been admitted on the last day reported (January 2). Twenty-four fatal cases occurred in the week ending December 21. For the four weeks ending December 28 the number of cases in hospital were 474, 506, 538, and 665 respectively, and the number of cases admitted were 170, 134, 161 and 225 respectively. The highest number admitted on one day was 42. The errors of diagnosis committed by physicians have been referred to several times in *THE JOURNAL*. In one case as many as 20 persons were infected in consequence of the failure to diagnose the disease: A married woman was taken suddenly ill. The doctor called in diagnosed blood poisoning, which he thought might have been due to a meal of oysters. Two other physicians were called in and also failed to recognize the disease. The patient got no better and the medical officer of health saw her on the eighth day, pronounced the case to be smallpox and ordered her removal. But she died before the ambulance arrived. The remaining members of the family were stricken one after the other. There are now in hospital, her husband, daughter, brother, 2 sisters, brother-in-law, 3 sisters-in-law and 6 other relatives. A man was found sorting letters at the postoffice with the disease developed; a girl with smallpox was selling Christmas toys; a boy affected was working a lift at a big store, and must have touched hundreds of people in the day. An emergency hospital of 300 beds is being erected which will raise the number of available beds to 1600. Following what appears to be a German example, several of the public health boards have made chicken-pox a notifiable disease, so that the Medical Officer of Health may be able to visit them and detect cases of misdiagnosed smallpox. In the Borough of St. Pancras 115 cases of chicken-pox were notified in 9 weeks of which 2 were found to be cases of smallpox.

##### Prevention of Tuberculosis—The Ventilation of Workrooms.

The National Association for the Prevention of Tuberculosis, to whose influence the recent highly successful British Congress on Tuberculosis was due, has not lost any time in endeavoring to give effect to the resolutions of the Congress. It has just issued a circular to the various employers' associations pointing out the importance of ventilation in the workrooms. The council of the association state that they are confident that if sufficient fresh air is supplied to the workers there will be a great reduction in all kinds of lung diseases, especially consumption and that their power of work will be enhanced, which means a saving to the employer greater than any outlay involved. In the British Army and Navy enormous losses in

former years were reduced to less than a third by better ventilation and drainage.

#### The Health of London.

The ninth annual report of the Medical Officer of Health for London recently issued contains much interesting information. The population now approaches five millions. The death-rate of the last 50 years shows a steady improvement. Thus the rates per 1000 in the decades 1841-50, 1851-60 and so on to 1881-90 were respectively 24.8, 23.7, 24.4, 22.5, 20.5; in the years 1891, 1892, etc., to 1900, 20.5, 21.0, 20.3, 21.0, 17.4, 19.5, 18.2, 17.3, 18.4, 19.6 and 18.6. The death rate of London, corrected for age and sex distribution in 1900, was only 20.4, while that of other great but much smaller towns was: Manchester (population, 548,700) 27.3; Birmingham (519,000), 23.8; Liverpool (634,000), 28.2; Leeds (431,000), 22.2; Sheffield (305,000), 25.1. During the decennium, 1891-00, as compared with 1881-90, there has been a mean annual saving of 3664 lives. In connection with the present epidemic of smallpox the number of cases in past years is of interest. From 1890 to 1900 the annual numbers are 40, 114, 425, 2815, 1193, 980, 225, 104, 33, 29, 86. Much of the smallpox of 1900 originated abroad.

#### Munificent Gift for the Erection of a Tuberculosis Sanatorium.

A donor, who wishes to be unknown, has placed at the disposal of the king the sum of \$1,000,000, to be applied for charitable or utilitarian purposes. His majesty has directed that this splendid gift shall be used for the erection of a sanatorium for tuberculous patients, and has appointed an advisory committee. [See *THE JOURNAL*, January 11, p. 117.] It is intended to construct the sanatorium in the best manner that experience and original thought can suggest. In order to obtain the most valuable opinions the sum of \$4000 will be awarded in prizes for the best essays and plans on the subject. Medical men of all nationalities may compete. The papers may either be the work of a medical man or the joint production of a medical man and an architect. The sanatorium is intended for tuberculous patients, 50 male and 50 female. Of the total number of beds 88 will be assigned to the more necessitous classes and 12 will be reserved for the well-to-do. The accommodation for all must be comfortable, a separate room being provided for each. The sanatorium will be erected on an elevated and sloping site, with a sunny exposure, and will be well sheltered from cold winds. It will have a farm at a convenient distance, and be surrounded by extensive grounds, well wooded and affording ample space for various kinds of exercises. The soil will be dry and permeable and the water supply abundant. The sanatorium will be fitted with the latest sanitary arrangements and equipped with all requirements for scientific research. All essays and plans must be sent, post-paid, on or before April 15, 1902, to one of the secretaries of the committee: Dr. P. Hoston Smith, 15 Upper Brook Street, London, W., or Dr. J. Broadbent, 35 Seymour Street, London, W. Three prizes of \$2500, \$1000 and \$500 respectively will be awarded in order of merit for the three best essays, provided they are of the requisite standard. Brevity will be an important consideration, and a summary of the main features of the scheme should be appended to the paper. Unsuccessful papers will be returned to the authors. [See *Foreign News*.]

#### Boycott of a Lady Doctor.

An extraordinary *imposse* has been brought about by the appointment of Miss Clarke, of Glasgow, as house surgeon to the Macclesfield Infirmary. Seven months ago the lady was appointed against the advice of the staff, who held that it was a great disadvantage to the institution and that the sphere of utility was much curtailed by placing a woman in the position of a house surgeon to attend to all sorts of ailments of male patients. Miss Clarke was then requested by the governors to resign and offered a quarter's salary. The hospital could not be carried on without the male staff of physicians, who were quite obdurate, declaring that they stood out on the grounds of principle. Miss Clarke was equally firm, and declared that she, too, was fighting on the grounds of principle—that of female employment—and refused all compromise. Matters were drifting into the position that by January 15 the Infirmary would have no male staff. However, Miss Clarke has been at last prevailed upon to resign, and the governors voted her a quarter's salary as a solatium out of the hospital funds. In addition a testimonial of \$500 has been collected by subscription of the governors and will be presented to Miss Clarke when she leaves, in a month.

**Rupture of Apparently Healthy Uterus During Labor.**

At the Edinburgh Obstetrical Society, Dr. Milne Murray related a case of this extremely rare accident. A woman aged 27 was pregnant with her fifth child. Pains began about 11.30 p. m., and at 2:30 a. m. she sent for a medical man, to whom she complained of severe pain, especially at a spot midway between the umbilicus and the left anterior superior iliac spine. He could not hear the fetal heart, and he noticed the tenseness of the uterine tumor, and its marked deflection to the left. There seemed to be no contraction to account for the pain complained of. On vaginal examination there was no sign of any presenting part; the finger could not be passed through the os, and the cervix was not taken up. The fetal parts could be felt with unusual distinctness at the upper part of the tumor. It was thought that the case was probably one of extra-uterine gestation. The patient was profoundly collapsed when Dr. Murray saw her. On vaginal examination under chloroform the finger passed through the os and found the cervix only partially taken up; the lower uterine segment was empty, and in the left side a rent in the wall could be felt through which the finger passed into the abdominal cavity. Laparotomy was performed and the fetus and placenta extracted. The rent in the uterus involved the left upper region of the bladder. There was alarming hemorrhage, both from the tear in the uterus and the torn uterine artery. The uterus was removed and the rent in the bladder was closed by fine catgut stitches. Owing to the patient's condition the operation was rapidly completed without peritoneal toilet. The patient did well until the thirteenth day, when her temperature rose. It continued high until the sixteenth day, but fell soon after a copious discharge of pus from the vagina. Recovery followed. The formation of pus was attributed to imperfectly sterilized ligatures. No cause could be found for the rupture. To the naked eye the uterus presented nothing abnormal and microscopic examination of tissue from the rent showed a perfectly normal structure. With regard to the variety of fluids, including meconium, which escaped into the peritoneum, Dr. Murray thought that if the material was not septic the less the peritoneal cavity was disturbed by attempts at cleansing the better. Of course, if septic matter were present it should be removed at all costs. Few cases have been recorded of rupture at the beginning of labor of a uterus without any gross complication. Such cases have been reported by Ingersley Hofmeier and Prof. A. R. Simpson. In the two first nothing abnormal could be found in the uterus; examination revealed nothing. In Simpson's case there was marked fatty degeneration of the muscular fibers.

**Inquest on a Peruvian Mummy.**

Conservatism and almost mechanical attachment to routine is well illustrated by the following exploit of one of the London coroners. A case containing a Peruvian mummy, intended for a Belgian museum, arrived in London and was opened. The man who opened it became frightened and reported the matter to the coroner. The latter held an inquest on the mummy. Under his direction the following grotesque verdict was brought in, "that this woman was found dead at the Railway Goods Station, Sun Street, on April 15, and did die on some date unknown in some foreign country, probably South America, from cause unknown. No proofs of violent death found and the body has been dried and buried in some foreign land, probably sundried and cave buried. The jurors are satisfied that this body does not show any recent crime in this country, and that deceased was unknown and about 25 years of age."

**Indian Sanitation.**

A comprehensive blue-book, containing a report on sanitary measures in India during 1899 has just been issued. The European troops appear to have enjoyed better health than in the previous year. On an average strength of 67,697 the admissions to hospital were in the ratio of 1149 per 1000, against 1437 in 1898. The chief cause of mortality was typhoid fever, which was responsible for 40 per cent. of the total deaths. Of causes of sickness the list is headed by ague and venereal diseases, the latter being responsible for 27 per cent. of the total illness, and over 20 per cent. of the invaliding. The loss by invaliding to the army was 2142. The health of the native army was also better than in 1898. Ague was the principal cause of illness. For venereal disease, the admission rate was only 34.1 per 1000, as compared with 313.4 in European troops. For the general population the year was healthy. A higher birth-rate resulted from the recovery from famine. The death-rate was 29.95. The number of successful vaccinations was 7,437,916. There are 2472 hospitals and dispensaries in India. The number of in-patients was 355,769, out, 20,238,917. The reports on the progress of sanitary work, water supply, and drainage from different cities and provinces were most satisfactory.

**Correspondence.****Human and Bovine Tuberculosis.**

BROOKLYN, N. Y., Jan. 6, 1902.

To the Editor:—Your editorial entitled "Human and Bovine Tuberculosis," published in your issue of the 4th inst., contains so many errors that it is surprising that it should appear in the columns of a reputable journal.

May I inquire how you know that the "experiment was poorly conceived" and "lacked many of the essentials for a satisfactory scientific proof of what it was intended to show"? Your only authority must have been the daily press, to the representatives of which I declined to give the details for the reason that I did not desire the publicity it would entail before the test was finished. As usual, the story was made up from meager information largely obtained from hearsay, and it went out as coming from me. Had you wished to know the truth of the matter, I would gladly have furnished it at your request. A journal purporting to be scientific in character should be more careful of its facts.

Again, you say that the experiment "is at last discredited by the findings of the Brooklyn health authorities that his inoculated cow did not have tuberculosis." This is absolutely false. I have before me the sworn statement of Dr. Ackerman, veterinarian of the Board in question, which states that he condemned the cow because it was tuberculous. A copy of this document is at your disposal should you desire to see it. The veterinarian who assisted me in the experiment with the cow (Dr. Walter L. Bell, of this city), also says the same thing. And I myself found tubercle bacilli in a gland taken from the axilla of the animal and my findings were corroborated by a medical friend who is an expert in that line. In view of these facts it is fair to presume that your statement that my experiment with the cow was a failure, is erroneous.

Your strictures upon the inoculation of the human being are also entirely uncalled for, when it is considered how little you know about the case. When the whole truth concerning it shall have been made public, it will be found that my efforts to advance medical knowledge will be completely justified.

GEORGE D. BARNEY, M.D.

Our comments on the case were based on a published statement by Dr. Cyrus Edson, which he has informed us was

dictated as dictated by him. He says: Dr. Barney refused to permit me to see or examine the young woman upon whom he has experimented, and forced me to rely entirely upon his own statements regarding the experiment. Accepting all his statements as true, I am led to an inevitable conclusion—namely, that he has demonstrated nothing, and that his experiment is of no scientific or practical value.

We now come to the consideration of the alleged inoculation of a human being with the diseased products of this cow. Dr. Barney told me that on November 9 he inoculated a young woman with infective material taken from the cow and that he has succeeded in producing the symptoms of tuberculous disease in the person so inoculated; that on December 5 a prominent specialist in lung diseases examined the patient and declared that she was suffering from tuberculosis, and that two days later another specialist examined the patient and made the same diagnosis. Dr. Barney refused to give me the names of these specialists. He claims that he now has the patient under treatment and expects to effect a cure.

And now as to the ethics in this case. Assuming for the moment that the cow did have tuberculosis and that the disease germ was injected by Dr. Barney into the girl's neck and that she developed tuberculosis, all of which is alleged by Dr. Barney, there could be but one opinion concerning the ethics of an experiment of this character. This opinion the reader may form himself from questions I put to Dr. Barney and his answers. I asked: "Dr. Barney, do you claim to cure 100 per cent. of your cases?" He replied: "No. I can cure 92 per cent. in the first stage of the disease."

"Then, how do you know," I asked, "that you have not killed this girl?"

Dr. Barney hesitated, turned color and replied rather incoherently and certainly not to the point: "I did this simply to make assurance more certain."

The numerable sources of error which interfere with medical investigation render imperative a great series of experiments in order to prove even the simplest medical fact. It is impossible from one or two experiences to attribute a given result to a definite cause. In no line of science is it so difficult to demonstrate the difference between cause and effect.

From the above, and the allegations of Dr. Barney in the context not quoted, it seems to us that we were fully justified in saying that the experiment lacked many of the essentials of a scientific demonstration. In the first place, it is a long way from demonstrating that the dangers of ingestion of tuberculous meat or milk are practically *nil*, even if direct inoculation does

produce the disease. Moreover, any one experiment can prove little; there are too many possibilities to be considered. Only a long and painstaking investigation could be absolutely conclusive. Dr. Barney's alleged claim seems to us altogether premature, the more so since he withholds details. If he has tried to avoid publicity he has been most unfortunately unsuccessful, and we believe that a serious attempt at privacy ought to have succeeded. As regards the ethical question we shall not retract our strictures on the alleged experiment on the young woman. It is not necessary to know any more about the case than has become, as it were, common knowledge to justify the condemnation. There are in medicine conditions in which it might be justifiable to risk life for the good of others, but we do not see them in this case, and can only reiterate our opinion that if the experimenter had experimented upon himself the case would have had at least a better moral aspect and the opportunities for obtaining anything of value from the results could not have been any worse. —EDITOR.

#### A Visit to Finsen's Institute.

CHICAGO, Dec. 30, 1901.

*To the Editor:*—Copenhagen is proud of its famous citizen. The kingdom of Denmark has contributed a sum of money sufficient to erect quite an imposing structure to house the Institute.

The Institute is located in a fashionable quarter of the city. The site was chosen on account of its seclusion. The residents strongly objected, but without avail, as it was decided that the unfortunate lupus patients needed such an environment of retirement and refinement in order to while away the long weeks of treatment.

The attendants are polite and are more than anxious to explain the operation of the remedial agent. They claim to cure 90 per cent. of all cases. To prove this they show you a large album of photographs of patients on entering and leaving the Institute. The transfiguration truly borders upon the marvelous. The once repulsive features are changed into those of a normal being. It is an interesting sight to watch the patients from every part of Europe walking up and down the corridor arm in arm waiting their turn for treatment.

In the amphitheater, which consists of one large square room, you are at once enveloped in an intense red glare coming from the electric globes. There are six 22,000 candle power arc-lights, shuded with red paper. They remind you very much of piano lamps. About each lamp six patients recline, each upon an elevated couch, with a nurse standing by his or her side. The light is so glaring that both patients and nurses have to wear dark glasses. Each patient requires a separate nurse, for it is necessary to hold continually a disc firmly pressed against the face, through which the light is projected. The tubes that direct the light upon the affected surface look very much like telescopes. There is one tube for each patient. The purpose of the telescopic arrangement is that all the heat rays shall be eliminated, and only the chemical, consisting of the blue, violet and ultra-violet, allowed to pass on. For it appears that they alone possess the bactericidal power. The exclusion of the yellow and red rays is effected by an ingenious combination of lenses together with the assistance of water. The treatment consumes one hour. Though the Institute is in full blast from 7:30 a. m. to 8 p. m. there is always a long waiting list. The power to furnish the arc-lights is in the basement immediately beneath the operating room. It was necessary to have their own plant in order to generate the extreme amount of electricity required.

Professor Finsen first employed sunlight in his experiments, but soon discovered that the sunshine in that climate was too uncertain. Patients come here from all parts of the world. The Institute is very democratic, for there is no distinction in race, color or condition. They are all treated alike.

The average time for a case is about seven months, or it may require more than a year. Some mild cases recover in a few weeks.

The charge to a Dane is \$18 per month, to an outsider \$30. But since all Denmark is so enthusiastic over it, a Dane,

though without the means, can have his expenses defrayed by the district from which he comes.

As these patients on account of their unsightliness experience great difficulty in obtaining lodgings, two shrewd former patients established a boarding-house and their enterprise has been richly rewarded.

A. K. WARNER, M.D.

#### National Board of Medical Examiners.

DETROIT, January 12, 1902.

*To the Editor:*—Permit me to make a few remarks concerning the editorial, "National Board of Medical Examiners," in the last issue of THE JOURNAL. I should like to take exception to the statement: "Without taking space to give our reason, we believe the ultimate results of reciprocity, as now understood, would be to lower rather than to elevate the standard." This statement is erroneous. Aside from this remark, however, I should like to endorse, very emphatically, the ideas expressed in the editorial. The opinion has been expressed also by me, some time ago, that "the most desirable regulation of the license to practice medicine would come from a National Board controlling the whole of the United States." I also said that our Constitution prevents this solution at present. The solution advocated in the editorial comes nearest to this. You mention as cardinal points:

1. A Board of Examiners which shall have authority to grant licenses that shall be recognized throughout the country.
2. The examination should in part be conducted in hospitals and laboratories, i. e., they shall be practical.
3. A fair standard of preliminary education should be required.
4. The applicant shall be a graduate from a reputable medical college.

I should like you to add:

5. The National Board shall inspect the medical colleges and decide which colleges can be regarded to be of a high standard as to teachers and teaching facilities.

Practical considerations may, perhaps, show that more than nine members may be required on the Board, and that a subdivision may be necessary. Taken as a whole, I must admit that a more ideal solution of the complex problem may not be found, at the present time. I, therefore, take occasion to recommend, most heartily, the institution of a National Board of Examiners as suggested in your editorial and I hope that decided steps will be taken at the next meeting of the American Medical Association to advance the solution of a question which is of such great importance for the public as well as for the medical profession. Meanwhile the establishment of interstate reciprocity on the basis of uniform medical legislation should be furthered by all possible means.

Very truly yours,

EMIL AMBERG, M.D.

Secretary of the Committee on Uniform Medical Legislation of the Conference of the Committee on National Legislation of the American Medical Association and Affiliated Societies.

PEKIN, ILL., Jan. 11, 1902.

*To the Editor:*—I have just read your editorial in to-day's number of THE JOURNAL, and it occurs to me that there is an easier and simpler way of deciding as to professional qualifications than any yet proposed. The primary object of all medical legislation is to protect the people from the ravages of the army of charlatans that infest the country. Does it succeed? No. Look at our own Illinois, the pioneer in medical legislation: Chicago is full of quacks. Peoria, Quincy, Springfield, and every other city in the state is infested with them. Even in Pekin we have a "magnetic healer" that can not spell *sugar*, and I am told he is making more money than any competent practitioner in town. Then we have Eddyites galore, and a few Dowieites just out of town. Notwithstanding all this infringement upon the intent of the law, the most learned professor in the country outside of Illinois could not practice here without passing the required examination. The Army, the Navy and the Marine-Hospital services will continue their examinations as usual. It is with the State Examining Boards

that I am concerned. They usually adopt their own special rules as to qualifications. Now, in transferring from one state to another, why not accept membership in the American Medical Association as evidence of necessary qualification? Each member is also a member of his state and local societies; he has the recommendations of all these, and this, it seems to me, should be sufficient evidence of fitness, and should be so recognized by all state boards. Very respectfully,

JNO. I. SKELLY, M.D.

## Book Notices.

EXPERIMENTELLE UND KRITISCHE BEITRÄGE ZUR HAENDEDESINFECTIONSFRAGE. Von Dr. Richard Schaeffer, in Berlin. Mit 12 Tabellen und 4 Abbildungen auf 2 Tafeln. Paper. Pp. 110. Berlin: Verlag von S. Karger. 1902.

This monograph gives the details of investigations and experiments in regard to the important question of hand disinfection in surgery. The author finds as a result of his studies that even the most careful washing and brushing of the hands and the employment of very hot water and numerous changes, even for a long time, will still leave numbers of germs upon the skin. The employment of sand and sterile towels scarcely perceptibly diminishes their number. The employment of asepsis such as sublimate, lysol, etc., are not sufficient to effectively reduce the number; they may reduce the number of colonies in cultures but not destroy them entirely or leave the hand in a safe condition, nor can we expect any very germicidal action of alcohol. That in his experiments he produced 1000 colonies from filtered debris of alcohol employed is one of the most satisfactory confirmations, in his opinion, of these views. Alcohol, however, is excellent as a mechanical cleansing agent and can so reduce the number of germs, especially in addition with hot water, as to make the danger of infection small. It is also on theoretic grounds advisable that the hands should be bathed in a sterile fluid, the most satisfactory for which would be a 1 per cent. sublimate solution. As regards the question of gloves he believes that if they do not seriously affect the tact sense their employment is in the line of surgical asepsis. The impermeable gloves, other things being equal, are still better than those which are permeable. The importance of quick and accurate operation is dwelt upon, leaving of smooth wounds and the avoidance of tears, etc., in operations. We can not avoid air infection, which is even more uncontrollable than that of the hands, and, therefore, the quicker the danger is past the less the chance of infection. For slight operations, infection even without the use of gloves can be practically excluded if care is taken as to this detail. In severer operations, of course, it may be impossible. The subject is one that requires still more study and experiment to give thorough satisfaction in regard to the possibilities. The work seems to be a rather important memoir on this specially important subject.

STUDIES OF THE INTERNAL ANATOMY OF THE FACE. By M. H. Cryer, M.D., D.D.S., Professor of Oral Surgery, Department of Dentistry, University of Pennsylvania. Cloth. Pp. 176. With 151 illustrations. Philadelphia: S. S. White Dental Manufacturing Company. 1901.

The view that no illustrations are so true to nature as photographs is adopted by Dr. Cryer. His work (illustrated with half-tone illustrations from photographs of actual sections of the bones of the face and jaws) is the result of "an investigation during which hundreds of skulls have been dissected and studied." This is a marked departure from the methods of studying anatomy so long in vogue. The tissues as they exist in their relation to each other are beautifully shown.

The illustrations are reminders to the student of anatomy that, as the author remarks, "owing to the degeneracy of the face and jaws it is possible though doubtful that in a thousand bones two or three should be found which exactly correspond with the typical bones so pictured."

In the evolution of man, the face and jaws, as Talbot has shown, undergo arrests of development and more marked deformities may exist than any illustrated in this work, which is a gentle reminder to dentist and rhinologist alike to study the origin of these structures before undertaking special treat-

ment. The author has not fully mastered the law of economy of growth, now nearly twenty centuries old. His views as to the predominance of the cerebellum as a cause of prognathism will appear antiquated to modern anatomists. The work, while of value, has little anthropologic and biologic data.

A TREATISE ON MEDICAL JURISPRUDENCE. Based on Lectures Delivered at University College, London. By George Vivian Poore, M.D. (Lond.), F.R.C.P., Professor of the Principles and Practice of Medicine, University College, London. With Illustrations. Cloth. Pp. 533. Price, \$4.00. New York: Longmans, Green & Co. 1901.

These lectures, delivered at the University College, London, and taken in shorthand for the *Clinical Journal*, are reproduced in this work. Its ready colloquial style and illustrative remarks on the cases make it almost as interesting as a novel. It is especially adapted to English laws and usages and the references, of course, are made to the English statutes and practices rather than to the American, but that will not necessarily seriously affect its value to American readers. A few things here and there, as might be expected, are superficially treated, and it would not be entirely safe, for example, to follow the author's distinction as regards poisonous and non-poisonous mushrooms. There may be other slight inaccuracies, but we believe they are rather few, and on the whole the book will be a safe guide. Insanity is treated rather sketchily and much dependence seems to be placed upon the illustrations which we do not consider the best way of giving students an idea as to the different forms. In fact, the illustrations of insanity are very poor substitutes for actual experience with cases or really good descriptions, and the space taken up in this book might perhaps have been better filled. The book is one that can well be added to any specialist's library and would be convenient for consultation by both lawyer and physician.

MODERN OBSTETRICS, GENERAL AND OPERATIVE. By W. A. Newman Dorland, A.M., M.D., Assistant Demonstrator of Obstetrics, University of Pennsylvania; Assistant Obstetrician to the University Hospital; Associate in Gynecology in the Philadelphia Polyclinic; One of the Consulting Obstetricians to the Southeastern Dispensary for Women. With 201 Illustrations. Second Edition. Revised and Enlarged. Philadelphia and London: W. B. Saunders & Co. 1901.

This work deserves commendation, and that it has received what it deserves at the hands of the profession is attested by the fact that a second edition is called for within such a short time. Especially deserving of praise is the chapter on Puerperal Sepsis. The various forms of puerperal sepsis are classed under General and Local, and under these heads the different forms are discussed in a systematic, practical and altogether satisfactory manner. This chapter will unquestionably help to bring about more accurate and scientific diagnoses in these cases. The happy-go-lucky manner in which the terms "puerperal sepsis" and "puerperal infection" have been and still are used by many writers to indicate pathologic conditions which differ widely, is reprehensible, and all efforts toward a systematic and scientific classification of the various forms of puerperal infection are to be commended. Such an effort has been made by the author, and the degree of success attained is as great as could be expected in the present state of knowledge.

A TEXT-BOOK OF MEDICINE. Begun by the late Charles Hilton Fagge, M.D., F.R.C.P., Sometime Physician to Guy's Hospital. Completed after his death and since revised or re-written by Philip Henry Pye-Smith, M.D., F.R.S., Fellow of the Royal College of Physicians. Fourth Edition. In Two Volumes. Vol. I. Cloth. Pp. 1123. Price, \$6.00 net. Philadelphia: P. Blakiston's Son & Co. 1901.

This is a well-known standard text-book in Great Britain, but it has never obtained anything but a fair recognition in this country. The general arrangement and method of presenting the subject is unique but excellent. The work was originally written by Dr. Charles Hilton Fagge, who died in 1883, leaving the manuscript practically completed, but the book did not appear until two years later. Since then it has reached the fourth edition and, as is stated in the preface, "there is scarcely a page of the late Dr. Fagge's work as he left it at the time of his premature death in 1883." Although, as a rule, the book is up to date, some parts of it do not bear strong evidence of this. None of the literature on yellow fever is referred to a later date than 1897, and the recent discoveries regarding the transmission of malaria are not mentioned. The section on "Tuberculosis" might have been written ten years ago, so far

as it refers to modern ideas. As a whole, however, the work is thoroughly reliable and with few equals as a text book on general medicine.

**NEUROLOGICAL TECHNIQUE. Some Special Histological Methods Employed for the Study of the Nervous System. Together with a Laboratory Outline for the Dissection of the Central Nervous System and the Neurological Nomenclature (HNA) Arranged in a Classified List.** By Irving Hardisty, Ph.D., Instructor in Anatomy, the University of California. Cloth. Pp. 183. Price, \$1.75 net. Chicago: The University of Chicago Press. 1902.

The University of Chicago Press has sent out this volume, which ought to be a very useful one for consultation by asylum, hospital and other physicians who have the opportunity to make anatomic preparations of the nervous system. The recognized methods are described both for the preparation of sections and of dry and wet specimens for museum purposes, with also directions for dissection and postmortem work. We do not know any other book of its size that seems quite as complete and useful as the present one, and none, of course, that ought to be more up to date. The anatomic nomenclature of the Basel commission is given in the concluding chapter as far as it covers the nervous system, and is a very useful feature.

**THE DIAGNOSIS OF NERVOUS AND MENTAL DISEASES.** By Howell T. Perthing, M.Sc., M.D., Professor of Nervous and Mental Diseases in the University of Denver. Illustrated. Cloth. Pp. 223. Price, \$1.25 net. Philadelphia: P. Blakiston's Son & Co. 1901.

The object of this little work as stated by the author is to facilitate the recognition of disorders of the nervous system and mind by those who are not specialists in the departments of neurology or psychiatry. It is, therefore, simply a compilation of facts and in the main, especially as regards the neurological side, judiciously made. We do not think that its classification of mental disorders is exactly that which is coming to be most generally accepted, and some of the types and diagnostic symptoms will not be of such service as will be the case with those in regard to nervous diseases proper. The author largely follows the etiologic classification and recognizes a number of types of mental disease which really have no clinical existence, in our opinion. This, however, is of minor importance. As a guide in medical diagnosis of diseases of the brain and nervous system it will be found decidedly serviceable to the general practitioner.

**ATLAS AND PRINCIPLES OF BACTERIOLOGY, and Text Book of Special Bacteriologic Diagnosis.** By Prof. Dr. K. R. Lehmann, Director of the Hygienic Institute in Würzburg, and R. O. Neumann, Dr. Phil. and Med., Assistant in the Hygienic Institute in Würzburg. Authorized Translation from the Second Enlarged and Revised German Edition. Edited by George H. Weaver, M.D., Assistant Professor of Pathology, Rush Medical College, Chicago. Part II. Text. Part I. Atlas. Philadelphia and London: W. B. Saunders & Co. 1901.

The present volumes of Saunders' well-known series of Medical Hand Atlases are fully up to the standards of the previous books in this series. These two volumes on bacteriology contain a vast amount of essential information conveniently arranged. The illustrations are many of them striking and can not but be of service to all engaged in general work in bacteriology, more particularly students. The translation is good, and the work of the editor has improved the text very materially, especially in correcting numerous mistakes in the references of the original to the literature and in verifying and correcting references to the plates. References to articles in English have also been inserted.

**TEXT-BOOK OF MEDICINE FOR STUDENTS AND PRACTITIONERS.** By Dr. Adolf Strümpell, Professor and Director of the Medical Clinic at the University of Erlangen. Third American Edition. Translated by Permission from the 13th German Edition, by Herman F. Vickery, A.B., M.D., Instructor in Clinical Medicine, Harvard University; and Philip Coombs Knapp, A.M., M.D., Ex-President of the American Neurological Association; with Editorial Notes by Frederick C. Shattuck, A.M., M.D., Jackson Professor of Clinical Medicine, Harvard University. With 185 Illustrations in the Text, and One Plate. New York: D. Appleton & Co. 1901.

A book which has reached thirteen editions in the original language and three in its English translation does not require any extended notice at this time. Suffice it to say that since the second edition of this English translation appeared in 1893, seven new editions have appeared in Germany so that the book has been almost wholly rewritten and must be considered as fully in line with the most recent knowledge. The translators have added a chapter upon the bubonic plague, and notes that may be of assistance to the American physician.

Dr. F. C. Shattuck has made a number of editorial notes, which also increase the value of the work.

**THE DIAGNOSIS AND TREATMENT OF DISEASES OF THE RECTUM. Being a Practical Treatise on Fistula, Piles, Fissure and Painful Ulcer, Proctitis, Polypus, Stricture, Cancer, etc.** By William Allingham, F.R.C.S. Eng., Ex-Member of Council of the Royal College of Surgeons of England; and Herbert W. Allingham, F.R.C.S. Eng., Surgeon to the Household of His Majesty the King. Seventh Edition. Cloth. Pp. 471. Price, \$3.25. New York: William Wood & Co. 1901.

This work is a leading English publication on its subject. The changes which have been made as given by the author are condensation where possible and such slight alterations as the advances of rectal surgery require, chiefly in the matter of excision of the rectum and inguinal colotomy. The work is rather full in its notice of American literature, though it makes no mention whatever of Martin's valves, the existence of which is one of the much discussed questions among American proctologists. The work is well issued by Wood and Company, and ought to be a useful addition to American literature on the subject.

**DISEASES OF THE NOSE AND THROAT.** By Cornelius G. Coakley, M.D. Second Edition. 12mo. Pp. 556. Philadelphia and New York: Lee Brothers. 1901.

This book is a summary of many well-known books on Diseases of the Nose and Throat, and of recent literature, but it contains nothing new, and the facts are not presented in a novel manner. It might be a handy book for physicians who wish now and then to brush up hastily on the diseases of which it treats, but it can not be especially recommended for those who desire precise information upon these subjects. The recommendation of a 10 per cent. solution of cocaine for nasal anesthesia does not appear judicious. It is certain that many patients will be unpleasantly affected by this strength, and much weaker solutions are quite efficacious.

**A HANDBOOK OF DISEASES OF THE NOSE AND PHARYNX.** By James B. Ball, M.D. (Lond.), Physician to the Department for Diseases of the Throat, Nose, and Ear, West London Hospital. Fourth Edition. With 61 Illustrations. Cloth. Pp. 439. Price, \$2.25. New York: William Wood & Co. 1901.

This book presents no great changes from the previous edition. It has been revised and a number of corrections and alterations have been made. The size remains nearly the same, there being no considerable addition to the number of pages as found in the third edition. The various subjects are treated quite comprehensively and more fully than in most handbooks. The writing is logical—the text self-explanatory. To the senior student and practitioner, for whom it is designed, the book will be found instructive and quite satisfactory.

**A MANUAL OF MEDICINE.** Edited by W. H. Allchin, M.D. (Lond., F.R.C.P., F.R.S., Ed., Senior Physician and Lecturer on Clinical Medicine, Westminster Hospital. Volume III. Diseases of the Nervous System. Cloth. Pp. 417. Price, \$2.00. New York: The Macmillan Co. 1901.

This third volume of Allchin's Manual of Medicine comprises a consideration of the diseases of the nervous system and is a very reliable though an abbreviated compendium on its subject. Among the contributors are Drs. Sherrington, Taylor, Turner and others, all well known. The subjects seem to be well handled. In conclusion it gives a chapter on medical ophthalmology and one on the medical application of electricity, both of which are serviceable additions.

**FIRST AID TO THE INJURED AND AMBULANCE DRILL.** By H. Drinkwater, M.D. Cloth. Pp. 104. Price, \$0.40. Edinburgh and London: Ballantyne, Hanson & Co.

This is a very convenient little manual of first-aid, useful both as regards its descriptions and its illustrations, which are well selected and ought to be very serviceable. It would be well for many physicians who are not in daily contact with surgical emergencies to look into a little book like this once in a while to freshen their memories as regards what might have to be done. So far as we can judge it is one of the best of its kind and its size makes it very convenient.

**MICROBES AND HEALTH.** By Samuel J. Wilson, M.D., Detroit, Mich., Member Clinton County Medical Society. Cloth. Pp. 230. Price, \$1.00. Lansing, Mich.: Robert Smith Printing Co. 1901.

The author of this little work seems to be a faddist in his opposition to the germ theory of disease. His conclusions and reasoning are not convincing and not likely to be very influential with the profession.

## Married.

EDWARD HOWARD, M.D., to Miss Eliza E. Berryman, both of Denver, Co., January 1.

RAY K. BARRY, M.D., to Miss Harriett Wilson, both of East Aurora, N. Y., January 1.

VICTOR G. VECKI, M.D., to Mrs. Minnie A. Vecki, both of San Francisco, Cal., January 5.

BENJAMIN O. COATES, M.D., to Miss Mary Rose, both of Cleveland, Ohio, January 4.

WILLIAM A. REID, M.D., Checotah, I. T., to Miss Alice Leeper, of Virginia, Ill., January 1.

WILLIAM L. RAYL, M.D., to Miss Pearl A. Bates, both of Caledonia, Mich., January 1.

JAMES C. DURRUM, M.D., Clarksville, Texas, to Miss Parks, of Irvine, Ky., December 23.

ROBERT L. GALLAHER, M.D., Texas, to Miss Mae Rhea, of Knoxville, Tenn., January 7.

EDWARD H. KNITTLE, M.D., to Miss Elizabeth Neelan, both of Onslow, Iowa, December 25.

ALBERT CHARLES ZAISER, M.D., to Miss Grace Melcher, both of Burlington, Iowa, January 1.

C. E. WRIGHT, M.D., Oskaloosa, Iowa, to Dr. J. D. McIntosh, of Charles City, Iowa, January 1.

G. WOGAN HURSH, M.D., Columbia, S. C., to Miss K. G. Weidy, of Tamaqua, Pa., January 1.

WALTER ALDMOND HAGER, M.D., to Miss Harriet Campbell, both of South Bend, Ind., January 8.

WILLIAM BRIMBLE-COMBE, M.D., Carmi, Ill., to Miss Lucy Land, of Big Prairie, Ill., December 31.

EDWIN S. DAY, M.D., Earlham, Iowa, to Miss Sydna Comp-ton, of Bear Creek, Iowa, December 24.

FREDERICK E. SQUIRES, M.D., Livonia, N. Y., to Miss Maude E. Riley, of Geneseo, N. Y., December 31.

GEORGE E. SENKLER, M.D., St. Paul, Minn., to Miss Abigail Dickson, of Milwaukee, Wis., January 7.

RICHARD G. CALLIHAN, M.D., to Miss Nettie Roland, both of Luray, Mo., at Kahoka, Mo., Nov. 24, 1901.

EDWIN J. EVANS, M.D., Rockland, Mich., to Miss Katherine Leary, of Lake Linden, Mich., December 26.

CHARLES MILTON LEIGHTON, M.D., to Miss Nellie Gertrude Sherry, both of Portland, Maine, January 6.

ROBERT T. SPAIN, M.D., Des Moines, Iowa, to Miss Verena Theresa Kramer, of Keota, Iowa, January 1.

EDMUND C. SANDFORD, M.D., Worcester, Mass., to Miss Florence Bartling, of Berkeley, Cal., December 28.

ALEXANDER J. McCANNEL, M.D., Lakota, N. Dak., to Miss Lora Tompkins, of Grand Forks, N. Dak., December 18.

WILLIAM B. HUNN, M.D., McKinney, Texas, son of Dr. George Hunn, Shelby City, Ky., to Mrs. Mary Steele, of McKinney.

JAMES PERCY SNELLING LENFESTEY, M.D., De Pere, Wis., to Miss Caroline Agnes Hurlbut, of Green Bay, Wis., January 15.

EDWIN L. CARY, M.D., Whitewater, Wis., to Miss Elizabeth E., daughter of Dr. John M. Evans, Evansville, Wis., January 1.

H. S. VERNON, M.D., house-surgeon, Chicago Polyclinic and Hospital, to Miss Bessie Atwood, of Chicago, January 4. They will reside in Lewistown, Minn.

## Deaths and Obituaries.

**James Rodman, M.D.** University of Louisville, Ky., 1849, one of the ablest and best-known physicians in Kentucky, died suddenly of heart disease, January 10, at his home in Hopkinsville, aged 72. His death was wholly unexpected, as he seemed in his usual health and spirits on the day of his death. He practiced his profession in Hopkinsville for three years, when he went to Frankfort to erect the building for the Feeb'e-Minded Institute. Three years later he was made superintendent of the Western Kentucky Insane Asylum and remained in charge until 1889. Since that time he has retired from active practice and has acted only as consultant in exceptional cases.

**William C. Dixon, M.D.** University of Pennsylvania, Philadelphia, 1860, a neurologist, of Philadelphia, died after an

operation for appendicitis, January 10. He served throughout the Civil war in a hospital in Philadelphia. At the time of his death he was a visiting physician to the Pennsylvania Hospital for the Insane, and one of the examiners for the insane department of the Philadelphia Hospital.

**Joseph Diehl Thomas, M.D.** Bellevue Hospital Medical College, New York, 1869, a prominent physician of Pittsburgh, Pa., one of the founders of the South Side Hospital, a member of the local, county and state societies and the American Medical Association, and professor of genito-urinary diseases in the Western Pennsylvania Medical College, died at his home in Pittsburgh, January 8, aged 58.

**Charles Francis Carpenter, M.D.** University of Pennsylvania, Philadelphia, 1849, who practiced in Chester County until 1857, then moved to Louisville, Ky., where he practiced until 1898, when he returned to West Chester, died at that place, January 5, after a two weeks' illness from la grippe, aged 76. During the Civil war he had charge of the Army Hospital in Louisville.

**Royal B. Prescott, M.D.** Long Island College Hospital, Brooklyn, N. Y., 1866, for many years a practitioner and ophthalmologist of Nashua, N. H., member of many medical societies, medical director of the National Guard of the state from 1889 to 1894, and president of the local board of pension examiners, died at his home in Nashua, January 2, from pneumonia, aged 63.

**William Koonz, M.D.** University of Pennsylvania, Philadelphia, 1899, died about two months ago as the result of sepsis following a gunshot wound received while attending a wounded soldier during a scouting expedition in the Philippine Islands, aged 26. His remains were brought back to the United States and were buried in Philadelphia with appropriate ceremonies, January 3.

**Elwood Stanley, M.D.** Western Reserve University, Cleveland, Ohio, 1849, one of the oldest residents of Sandusky, Ohio, a member of the Erie County Medical Society and of the American Medical Association, who had served the county as coroner and the city as a member of the city council, died at his residence in Sandusky, January 4, after an extended illness, aged 78.

**James B. Shaw, M.D.** University of Glasgow, Scotland, 1836, who had been a resident of Santa Barbara, Cal., since 1850, and who practiced medicine for a short time only when he gave it up for the pursuit of sheep raising, died at his home in Santa Barbara, from pneumonia, January 7, aged 88.

**Ephraim M. Reynolds, M.D.** College of Physicians and Surgeons, Keokuk, Iowa, 1880, a member of the American Medical Association, a practitioner of Centerville, Iowa, and formerly state senator, died January 8, at his home in Centerville. His death is said to have been brought on by excessive work in the practice of his profession.

**Richard W. Hill, M.D.** University of Iowa, Iowa City, 1883, for many years professor of anatomy and physiology at the Iowa State University, local surgeon for the Rock Island road and a member of the medical staffs of several hospitals, was found dead in his bed at Davenport, from heart disease, January 10.

**Daniel Waldo Stearns, M.D.** Harvard University Medical School, 1888, a native of Newton, Mass., died at his home in that city, January 9, after an illness of two days from kidney disease, aged 37. He was a member of the Massachusetts Medical Society and had served as a member of the common council.

**William H. Williams, M.D.** Yale Medical School, New Haven, Conn., 1847, a practitioner of Brooklyn for more than half a century, a member of the Kings County, New York State and American Medical Associations, died at his home in Brooklyn, January 3, aged 79.

**C. Jane Vincent, M.D.** Woman's Medical College of Pennsylvania, Philadelphia, 1882, for twenty years a practitioner of Allegheny, Pa., and a member of the local and state medical societies, died at her home in Allegheny, January 7, from acute indigestion, aged 48.

**Norbourne N. Shipman, M.D.** Medical College of Ohio, Cincinnati, 1874, who had practiced medicine in Seymour, Ind., for a quarter of a century, and was secretary of the Jackson County Medical Society, died at his home in Seymour, January 7, aged 72.

**Phineas I. Mulvane, M.D.** Rush Medical College, died at his home in Chicago, January 10, aged 64. His early practice

was in Bureau County, Ill., whence he moved to Topeka, Kan., where he practiced 17 years, returning to Chicago last year.

**Burk Priddy, M.D.** University of Nashville, Tenn., 1874, a highly esteemed physician of Logan County, Ark., who had represented that county in the legislature during two sessions, died at his home in Magazine, January 31, from pneumonia.

**Edward Steese, M.D.** Cleveland (Ohio) Medical College, a retired practitioner of Brookline, Mass., and a member of the Brookline Medical Club, died at his home in that place, January 6, after a prolonged period of invalidism, aged 57.

**Thomas A. Carrico, M.D.** a prominent physician of Charles County, Md., died at his home in Oakland, near Bryantown, January 5, aged 74. He had practiced for more than half a century and served three terms in the legislature.

**Gazaway B. Knight, M.D.** Medical College of Georgia, Augusta, 1848, who was an active practitioner of Madison, Ga., until his retirement, ten years ago, died at his home in that place, January 3, after a short illness, aged 76.

**J. J. Buchanan, M.D.**, assistant surgeon, U. S. Navy, and assigned to duty on the *Constellation*, committed suicide while delirious from typhoid fever at the naval hospital at Coates Harbor Island, January 12, aged 24.

**Harry J. Griffith, M.D.** Medical College of Ohio, Cincinnati, 1897, a promising practitioner of Morgantown, Ind., died at the Deaconess' Hospital, Indianapolis, January 2, after an operation for appendicitis, aged 27.

**G. C. Gray, M.D.** Missouri Medical College, St. Louis, Mo., 1882, one of the leading physicians of Harvel, Ill., died at his home in that place, December 23, after an illness of nine days, from pneumonia, aged 52.

**Joseph S. Carreau, M.D.** New York University, 1874, who had recently returned from a stay of two years in Europe, died suddenly from heart disease in his apartments in New York City, January 7, aged 53.

**A. Howell, M.D.** University of Buffalo, N. Y., 1865, a practitioner of Eagle Bend, Minn., and a veteran of the Civil war, died at his home in that place, December 28, after an operation for hernia, aged 61.

**Smith T. Ferguson, M.D.** Rush Medical College, Chicago, 1895, a prominent physician of Joliet, Ill., and at one time physician to the State Penitentiary, died at his home in Joliet, January 10, aged 56.

**John R. McDonald, M.D.** University of Nashville, Tenn., 1867, one of the best known physicians in the Tennessee Valley, died at his home in Courtland, Ala., January 6, from pneumonia, aged 58.

**Elizabeth A. Darby, M.D.** Woman's Medical College, Baltimore, 1896, a practitioner of Providence, R. I., died there, January 1, from the effects of a self-inflicted gunshot wound, aged 32 years.

**Justinian K. Piersol, M.D.** University of Buffalo, N. Y., 1872, a prominent physician of Adrian, Mich., died at his home in that city, January 2, after a lingering illness, aged 67.

**William Augustus Pierrepont, M.D.** University of New York, 1882, a retired practitioner of Brooklyn, N. Y., died January 6, after a short illness, from heart disease, aged 46.

**Samuel S. Shamhart, M.D.** College of Physicians and Surgeons, Keokuk, Iowa, 1896, died at his home in Hyattville, Wyo., as the result of an overdose of chloral, January 2.

**Joshua M. Doan, M.D.** a prominent young physician of North Bend, Neb., died from the effects of an accidental gunshot wound, at the Fremont Hospital, January 6, aged 27.

**George W. James, M.D.** Rush Medical College, Chicago, 1865, who had practiced in Lawson, Mo., for thirty years, died at his home in that place, January 2, aged 64.

**John D. Young, M.D.** Kentucky School of Medicine, Louisville, 1865, a well-known physician of Central New York, died at his home in Starkville, January 7, aged 70.

**Leroy E. Jones, M.D.** Geneva (N. Y.) Medical College, 1845, one of the oldest practitioners in New York State, died at his home in Buffalo, January 6, aged 81.

**Charles Schaper, M.D.** Rush Medical College, Chicago, 1885, a practitioner of Franklin, Wis., died at his home in that place, December 29, from consumption, aged 42.

**Frank M. Hayes, M.D.** Western Pennsylvania Medical College, Pittsburg, 1893, died at his home in Allegheny, Pa., January 2, from pneumonia, aged 40.

**James S. Whedon, M.D.** Geneva (N. Y.) Medical College, 1866, who practiced in Syracuse from 1877 to 1899, died in Jordan, N. Y., December 26, aged 57.

**William W. Young, M.D.** University of Pennsylvania, Philadelphia, 1894, died at his home in Nanticoke, Pa., January 6, from sepsis resulting from a felon.

**Lee A. Loggins, M.D.** Washington University, St. Louis, 1898, a practitioner of Graham, Texas, died at the house of his father in Ennis, Texas, December 27.

**A. L. Nichols, M.D.** Rush Medical College, Chicago, died at his home in Ludington, Mich., December 28, after a two weeks' illness from typhoid fever, aged 36.

**Charles C. Garrett, M.D.** Rush Medical College, Chicago, 1849, was burned to death while sleeping in his office at Calvert, Texas, December 26, aged 83.

**Luther Lagle, M.D.** University of Louisville, Ky., 1886, a practitioner of Gainesville, Texas, died from paralysis after a short illness, December 27.

**Andrew J. Christensen, M.D.** Washington University, St. Louis, 1873, died January 7, at his home in Waukon, Iowa, from pneumonia, aged 75.

**Scott C. Newcomb, M.D.** Bellevue Hospital Medical College, New York, 1895, died at his home in Walpole, Mass., December 31, from heart disease.

**W. W. Hibbard, M.D.** Castleton (Vt.) Medical College, 1848, died at his home in Poultney, Vt., December 21, from pneumonia, aged 73.

**Charles Forbes, M.D.** University of Glasgow, Scotland, died from heart disease at the County Hospital, Georgetown, B.C., December 26.

**Shannon McRill, M.D.** College of Physicians and Surgeons, Keokuk, Iowa, 1897, at his home in Victoria, Ill.

## Miscellany.

**Food of American Soldiers in the Tropics.**—The following is from the annual report of Major-General Lloyd Wheaton, U. S. Army, commanding the Department of Northern Luzon, P. I., for the year ending June 30, 1901: Contrary to theory, practical demonstration proves beyond a doubt that American soldiers serving in these islands need the full army ration, with the addition of more sugar. The same amount of first-class fresh beef is required as in Montana; health can not be maintained without an abundance of nutritious food carefully prepared. The foreign population in these islands, and the wealthy natives, are just as heavy eaters as are Americans; besides, they use a great deal of Scotch whiskey and red wine. The poor masses live on rice and fish, but not from choice. They are anemic and full of skin diseases, as the result of an impoverishing diet. Native scouts fed on the army ration soon get fat, change in appearance and gain in strength. In a number of instances many native prisoners of war, and other natives convicted of crimes, have been received at prisons suffering from beri-beri or skin diseases. The surgeons recommended the issue of the army ration, stating that such diseases were the result of an impoverishing diet of rice and fish. These diseases seem to have rapidly disappeared under the benign influences of the army ration. It has been suggested by some persons—not company commanders or their men—that a special ration should be issued to American troops serving in the tropics; but practical demonstration does not support any such opinions founded upon theory. Company, troop and battery commanders recommend no change in the ration except an increase in the amount of sugar, and the issue of oatmeal.

**Have We a Fraternity?**—The subject of medical ethics is one which is talked of a great deal by physicians, and probably practiced too little, or else we would have more harmony within our ranks. To do unto others as we would be done by, is a sufficient rule to follow, if we would but abide by its dictates, but how many can conscientiously claim to practice the same with professional brothers or neighbors? In the larger towns and cities it is expected that the profession should be more harmonious, but can that always be truthfully said? On the contrary, the larger the place the greater number of cliques or divisions, while in the country districts these divisions are limited, because there are fewer doctors. How many towns in the state are there in which the medical profession is a unit on the question of consultations? How many men are there who are members of the state or district

medical organizations who, for one reason or another, refuse to meet other practitioners who are also members of the same organizations? Let each member of our State Association examine himself and place a few of the interrogatives so as to ascertain whether or not his neighbor is altogether at fault. The lack of consideration for each other, and our petty prejudices formed for us by others, is the greatest producer of discord. When a doctor decides to change his location how many hands of good fellowship are extended to him by those in the field? Is it not probable that many a man would be more disposed to walk in the path of righteousness in his new sphere had he been given a welcome by those already located, and at least, better established than he? Now that we have the opportunity of raising the standard of medicine in our state through the instrumentality of the new law, it seems timely that we should ascertain whether or not we have a fraternity within our ranks.—*Texas Clinic*, October, 1901.

**Prizes Offered by the Paris Academie de Medecine.**—Works sent in to compete for these prizes must be received by the end of February of the year in question. Those not open to foreigners are omitted from the following list: The Academie prize of 1000 francs is, in 1902, for the best sealed article on toxins in pathology; in 1903, on means of determining the eliminating activity of the kidney; in 1904, on cirrhosis of the liver—clinical and experimental study. The Alvarenga prize is annual, 800 francs, for best article on any branch of medicine. Apostoli, 600, annual, on electrotherapy. Baillarger, 2000, 1902 and 1904, treatment of the insane. Barbier, 3000, annual, for a complete cure of affections hitherto considered incurable. Boullard, 1200, 1902 and 1904, for best work on or best results in treatment of mental affections. Bourceret, 1200, annual, circulation of the blood. Buisson, 10,500, 1904, for best discoveries with result of curing hitherto incurable disease. Dupierris, 2300, 1902 and 1904, for best work on anesthesia or affections of urinary passages. Capuron, 1000, sealed, 1902, relations between fibrous tumors of the uterus and pregnancy; 1903, action of saline waters on digestion; 1904, application of radiography to obstetrics. Chevallion, 1500, annual, cancerous affections. Civrieux, 800, annual, sealed, 1902, dementia; 1903, cerebral troubles in sclerosis in patches; 1904, rôle of syphilis in brain disease. Clarens, 400, annual, hygiene. Daudet, 1000, sealed, 1902, cancers; 1903, general medication in treatment of cancers; 1904, surgical treatment of neoplasms of large intestine, rectum excepted. Desportes, 1300, annual, practical medical therapeutics. Falret, 700, sealed, 1902, somnambulism; 1904, neurasthenia. E. Godard, 1000, annual, internal and external pathology. Guzman, income of 1328 francs, for actually effective treatment of organic heart disease. T. Herpin, 3000, annual, epilepsy and nervous affections. Herpin, 1200, sealed, 1902, abortive treatment of tetanus. Itard, 2400, 1903, for best treatise on practical medicine or applied therapeutics published at least two years. Jacquemier, 1700, 1904, for author of work on some obstetric subject which has realized an important progress. Laborie, 500, annual, medical statistics. Laborie, 5000, annual, for author who has materially advanced the science of surgery. Lefevre, 1800, sealed, 1902, melancholia. Lefort, 300, 1903, study of mineral and drinking waters. H. Lorquet, 300, annual, mental affections. Louis, 3000, 1904, serotherapy of typhoid fever. Mège, 900, sealed, etiology and pathogenesis of arteriosclerosis. Meynot, 2600, annual, affections of eyes and ears. Nativelle, 300, annual, for extraction of hitherto unisolated active principle of some drug. Orfila, 4000, sealed, 1902, alkaloids of belladonna, hyoscyamus and datura. Portal, 600, sealed, 1902, experimental research on inoculation and contagion of cancer; 1903, pathologic anatomy of salpingitis in relation to the causes producing it; 1904, comparative hematologic study of variola and vaccine. Pourat, 700, annual, sealed, 1903, secretions of microbes and their physiologic action in genesis of disease; 1904, circulation of blood in lung. P. Ricord, 600, 1903, venereal diseases. Saint-Lager, 1500, for person who succeeds in experimentally producing tumor of the thyroid by substances extracted from water or soil of countries where goitre is endemic. Saintour, 4400, 1902 and 1904, for best MS. or printed work on any branch of medicine. Stanski, 1500, 1902 and 1904, study of miasmatic contagion in epidemics in general or in a particular epidemic. Tremblay, 7200, 1903, affections of urinary passages. Vernois, 700, annual, hygiene. The Audiffred prize has been mentioned several times in *THE JOURNAL*. It is an endowed income of 24,000 francs for the person, without distinction of nationality or profession, who, before 1921, discovers a sovereign remedy that will cure or prevent tuberculosis.

## Societies.

**WATONWAN COUNTY (MINN.) MEDICAL ASSOCIATION.**—The annual meeting of this Society was held in St. James, December 11. Dr. Lanson L. McCurdy was elected president and Dr. W. J. McCarthy secretary, both of Madelia.

**SAMOSSET MEDICAL ASSOCIATION.**—The medical fraternity of Plymouth, Mass., met December 19 and organized this Association, with Dr. Wilfred G. Brown as president and Dr. J. Holbrook Shaw, vice-president and secretary.

**LANCASTER CITY AND COUNTY (PA.) MEDICAL SOCIETY.**—The following officers were elected at the annual meeting: Dr. Martin L. Herr, president; Dr. Park P. Breneman, secretary, and Dr. George R. Rohrer, treasurer, all of Lancaster.

**NEW BRITAIN (CONN.) MEDICAL SOCIETY.**—The tenth annual meeting of this Society was held January 2, when President Dr. George J. Holmes and Secretary and Treasurer Dr. Joseph B. Brocksieper were unanimously re-elected.

**ORANGE COUNTY (TEXAS) MEDICAL SOCIETY.**—The first meeting of this Society since its organization was held at Orange. The following officers were elected: Dr. J. Saunders, president; Dr. J. E. Reeves, vice-president, and Dr. M. Rives, secretary.

**PHILADELPHIA OBSTETRICAL SOCIETY.**—At the annual meeting of this Society, January 2, officers were elected as follows: President, Dr. John M. Fisher; vice-presidents, Drs. Richard C. Norris and Wilmer Krusent; secretary, Dr. Frank W. Talley, and treasurer, Dr. John W. West.

**SPRINGFIELD (OHIO) ACADEMY OF MEDICINE.**—The annual meeting of the Academy was held January 6. The following officers were elected: Dr. Read L. Bell, president; D. Walter Spence, vice-president, and Dr. Joseph A. Link, secretary. The annual banquet was held January 15.

**LOS ANGELES (CAL.) ACADEMY OF MEDICINE.**—At the annual meeting of the Academy, held December 27, Dr. Benjamin O. Webb was elected president; Dr. Frances O. Yost, first vice-president; Dr. Frances E. Corbin, second vice-president, and Dr. F. M. Pottinger, secretary and treasurer.

**MARION COUNTY (KAN.) MEDICAL ASSOCIATION.**—The physicians of Marion County met last month to organize a county medical association. Dr. Richard F. Harris was elected president and Dr. J. Allen Palmer, Florence, secretary. The first regular meeting will be held some time this month.

**BELMONT COUNTY (OHIO) MEDICAL SOCIETY.**—At the annual meeting of this Society, held recently at Bellaire, Dr. William L. Judkins, Barnesville, was elected president; Dr. J. A. Clark, Glen-coe, vice-president; Dr. Alfred C. Beetham, Bellaire, secretary, and Dr. James S. McClellan, Bellaire, treasurer.

**LANCASTER CITY (PA.) PATHOLOGICAL SOCIETY.**—At the annual meeting of this Society, held December 27, the following officers were elected: Dr. George L. Cassel, president; Drs. William H. Herr and Samuel W. Miller, vice-presidents; Dr. John W. Kinard, secretary, and Dr. Frank G. Hartman, treasurer.

**LANE COUNTY (ORE.) MEDICAL SOCIETY.**—The members of the regular profession of Lane County met at Eugene, December 21, and organized this Society with the following officers: Dr. William Kuykendall, president; Dr. Waldo L. Cheshire, vice-president, and Dr. John W. Harris, secretary, all of Eugene.

**AUSTIN (TEXAS) DISTRICT MEDICAL SOCIETY.**—At its annual meeting, held in Austin, December 20, the following officers were elected: Dr. William J. Mathews, Austin, president; Drs. E. Mat Thomas, Georgetown, and Cyrus O. Weller, Austin, vice-presidents; and Dr. W. A. Harper, Austin, secretary and treasurer.

**VIGO COUNTY (IND.) MEDICAL SOCIETY.**—The annual meeting and banquet of this Society were held at Terre Haute, January 2. Dr. W. E. Bell, Terre Haute, president; Dr. Richard Belt, West Terre Haute, vice-president; Dr. Cassius M. Smick, Terre Haute, treasurer, and Dr. Malachi R. Combs, Terre Haute, secretary.

**BOND COUNTY (ILL.) MEDICAL SOCIETY.**—The annual meeting of this Society was held at Greenville, January 2, when Dr. E. P. Poindexter, Greenville, was elected president; Dr. John A. Warren, Beaver Creek, vice-president; Dr. William T. Easley, Greenville, secretary, and Dr. W. C. Barnes, Mulberry Grove, treasurer.

**MADISON COUNTY (ALA.) MEDICAL SOCIETY.**—At the annual meeting of this Society, held in Huntsville, January 6, Dr. William D. Pettus, Rep., was elected president; Dr. Felix E. Baldridge, Huntsville, vice-president; Dr. Edgar Rand, Huntsville, secretary and treasurer, and Dr. William C. Wheeler, Huntsville, county health officer.

**MANITOWOC COUNTY (WIS.) MEDICAL SOCIETY.**—The annual meeting of this Society, held in Manitowoc, January 4, was the most successful session in its history. The following officers were chosen: Dr. William G. Kemper, Manitowoc, president; Dr. Louis Falge, Reedsville, vice-president, and Dr. Herbert Thurtell, Manitowoc, secretary and treasurer.

**CANTON (OHIO) MEDICAL SOCIETY.**—The annual meeting of this Society was held January 2. Dr. John P. DeWitt was elected president; Dr. Williams, vice-president; Dr. Wallace S. Foulks, recording secretary; Dr. J. Frank Kahler, corresponding secretary, and Dr. Frank Da Hinden, treasurer. Resolutions were adopted in memory of the late Dr. William McConkey.

**KANSAS CITY (MO.) ACADEMY OF MEDICINE.**—At the annual meeting of the Academy, January 4, Dr. James W. Gaines was elected president; Dr. Charles B. Hardin, vice-president; Dr. George W. Bellows, censor; Dr. John G. Lapp, secretary, and Dr. C. Lester Hall, treasurer. Dr. George W. Webster, Chicago, was the guest of honor at the annual banquet of the Academy, January 9.

**ELKHORN VALLEY (NEB.) MEDICAL SOCIETY.**—The seventh semi-annual meeting of this Society was held January 7, in Norfolk. The officers elected for 1902 were: Dr. John P. Gilligan, O'Neill, president; Dr. W. S. Summers, West Point, and John J. Williams, Wayne, vice-presidents; Dr. Joseph M. Alkin, Omaha, secretary, and Dr. William H. Hagey, Norfolk, treasurer. The Society meets early in January and July of each year.

**COLUMBUS (OHIO) ACADEMY OF MEDICINE.**—The annual meeting of the Academy was held December 17. The president, in his address, favored the reorganization plan of the State Medical Society which conforms to that of the American Medical Association. The

following officers were re-elected: Dr. James C. Lawrence, president; Dr. Ota S. Hendrixson, vice-president; Dr. John L. Gordon, secretary; and Dr. Francis W. Blake, treasurer.

**PHILADELPHIA COLLEGE OF PHYSICIANS.** At a stated meeting of the College of Physicians January 1, officers and elective committees for 1902 were chosen as follows: Dr. Horatio C. Wood, president; Dr. Arthur A. Meigs, vice-president; Drs. Richard A. Cleeman, Arthur A. Meigs, S. Weir Mitchell, and Horace Y. Evans, censors; Dr. Thos. R. Nelson, secretary; Dr. Richard H. Harte, treasurer; Dr. Frederick P. Henry, honorary librarian.

**UNION MEDICAL SOCIETY OF NORTHERN MICHIGAN.** This Society, whose membership is made up of the physicians of Ionia, Montcalm and Mecosta counties, held its second annual meeting at Belding, December 10. The following officers were elected: Dr. John Avery, Greenville, president; Drs. Charles S. Cope, Ionia, Leavitt S. Griswold, Big Rapids, William P. Gamber, Stanton, Francis R. Blanchard, Lakeview, and James E. Ferguson, Belding, vice-presidents; and Dr. Horace L. Bower, Greenville, secretary and treasurer.

**AMERICAN CHEMICAL SOCIETY.** On December 31, the American Chemical Society adjourned its 25th annual meeting, to meet again in July in Pittsburgh, Pa. Dr. Ira Remsen, President of Johns Hopkins, was made president of the Society. In an address describing formaldehyde generators, William Dreyfus, of New York, deprecated the vapor distillation followed in some cities, and argued in favor of the vapor method. At a banquet in the evening Dr. G. H. Meeker was one of the committee of reception. Dr. Wm. McMurrie, of New York, was one of those responding to toasts.

**STEEBEN COUNTY (N. Y.) MEDICAL ASSOCIATION.** The physicians of Steuben County held a meeting in Hornellsville, December 20, to organize an association to be known as the Steuben County Medical Association, which will be a branch of the New York State Medical Association. Dr. John G. Kelly, Hornellsville, acted as chairman. Committees were named as follows: Nomination, Drs. John S. Jambon and Frank H. Koyle, Hornellsville; by-laws, Dr. Victor C. Pederson, Corning. The committees are to report before the next regular meeting to be held at Hornellsville, February 3. The purpose of that meeting is to elect permanent officers and to perfect the organization.

**ALPHA KAPPA KAPPA FRATERNITY.** On January 2 and 3 the Alpha Kappa Kappa Fraternity (medical) held its seventh annual convention in Philadelphia. There are local chapters in Jefferson Medical College and the University of Pennsylvania. A memorial service marked the opening session. The convention ended with a banquet at the Hotel Colonnade January 3. Dr. Edward P. Davis acted as toastmaster. The following officers were continued in office: Grand president, Dr. George Cook, Concord, N. H.; grand vice-president, Dr. John I. French; grand secretary, Dr. J. H. Collins; grand treasurer, Dr. Edward R. Pfarre. The next meeting will be held in Chicago, January 2 and 3, 1903.

**ST. JOSEPH (MO.) MEDICAL SOCIETY.** The annual banquet of this Society was held December 31. Toasts were responded to by Drs. Jefferson D. Griffith and Blencowe E. Fryer, of Kansas City, and Drs. Jacob Gelker, Thompson N. Potter, Charles H. Wallace, and Wallace B. Deffenbaugh, of St. Joseph. Dr. John M. Bell, president of the Society, acted as toastmaster. The guests of honor on this occasion were Dr. Jefferson Davis Griffith, President of the Missouri State Medical Society, which meets in St. Joseph, next May, and Dr. Blencowe E. Fryer, Chairman of the Committee on Scientific Communications. Both of these gentlemen are sanguine regarding a large and most successful meeting of the State Society at St. Joseph.

**MILWAUKEE COUNTY (WIS.) MEDICAL SOCIETY.** The above-named Society has been incorporated without capital stock for "mutual professional advancement and the general good of the medical profession," by Drs. Edwin W. Bartlett, William F. Malone and Selden B. Sperry. The meeting for organization was held in Milwaukee, December 18, at which the need for such an organization and its possibilities were discussed. Dr. Edwin W. Bartlett was chosen temporary chairman, and Dr. Warren B. Hill, temporary secretary. At the first regular meeting, January 2, the Code of Ethics of the American Medical Association was adopted, and the following requirements for admission determined: The holding of a diploma from some regular medical school, a certificate of the state medical society, or a certificate of registration from the state board of medical examiners. The following officers were elected: Dr. Edwin W. Bartlett, president; Dr. Rudolph C. Teschan, vice-president; and Dr. Warren B. Hill, secretary and treasurer, all of Milwaukee.

## CHICAGO NEUROLOGICAL SOCIETY.

*Stated Meeting, Nov. 21, 1901.*

### Functions of the Cerebellum.

DR. LEWELLYS F. BARKER, spoke of the functions of the cerebellum, referring to the development of knowledge on the subject and its present status. The views held by Haller, Rolando and Weir Mitchell (cerebellum as a center of muscular energy), by Flourens and Wagner (cerebellum as a center of coordinating voluntary movements), by Gall (cerebellum as a center of sexual passion), and by Lussana (cerebellum as a center for muscular sense) were successively mentioned. The careful studies and experiments of Luciani were taken up in some detail and the opinions of the Italian investigator upon the sthenic, tonic and static action of the cerebellum reviewed; the researches of Ferrier, Schiff, Risien, Russell and Thomas were referred to. The weight of evidence at present is in favor of the view that the cerebellum is above all an organ upon the integrity of which the maintenance of normal equilibrium, under ordinary circumstances, depends.

An analysis of the cases in human beings in which the symptoms seen during life could, as a result of postmortem examination, fairly be referred to atrophy of the cerebellum, shows that the cerebellar symptom—complex as met with in man, corresponds very closely to that producible experimentally in animals.

The structure of the cerebellum was described at some length, the description being couched in terms of the neuron conception. The central neurons of the cerebellum, as well as the cerebellopetal and cerebellofugal conduction paths were discussed. The speaker expressed the opinion that a large part of the confusion existing among clinicians with regard to the nomenclature of nervous diseases depends upon the effort which is so often made to classify diseases according as the lesions accompanying them are distributed chiefly in one or another of the coarser macroscopic subdivisions of the central cerebro-spinal nervous system. The time was past, he thought, when we could satisfactorily use the terms, "Diseases of the Spinal Cord," "Diseases of the Cerebellum," etc., as headings under which to group the special diseases. A much more rational classification is that based upon the conduction paths and sets of neuron systems involved in the pathologic process. Thus, diseases in which the systema neuronicum spino-cerebellare dorso-laterale is degenerated affect the cerebellum as well as the spinal cord. The macroscopic subdivisions of the central system are so intimately connected with one another by means of neuron chains that a separation of the diseases of one from diseases of another is, as a rule, futile. When one considers the large number of neuron systems connecting the cerebellum with the spinal cord and rhombencephalon on the one hand, and with the cerebrum on the other, the number of possible permutations and combinations as regards lesions is seen to be very great. Why should not the clinical picture presented in different cases of diseases affecting the cerebellar neurons be extremely variable? The wonder is not that we have different types of disease which are somewhat closely allied to one another; it is much more that the clinical pictures presented in the various cases are so much alike as clinicians assert that they are. Possibly, when our methods of clinical differentiation have become more refined, we shall be able to speak more confidently than we can at present with regard to the exact neuron systems involved in a given case, or series of cases.

### Hereditary Cerebellar Ataxia, with Report of a Case.

DR. HUGH T. PATRICK said the affection was introduced into the nosology of nervous diseases by Marie, in 1893. He based his assertions of a clinical and pathologic entity upon cases reported by Fraser, Nonne, Sanger Brown, and Klippel and Durante. Dr. Patrick showed that while there was some resemblance between all of these cases and each group remained reasonably constant to its own type, they did not sufficiently agree either in clinical manifestations or pathologic anatomy to constitute a well-defined type. A brief review was given of cases published since 1893, and the same lack of adherence to a fixed type clearly illustrated. Microscopic examination of cases subsequent to the paper of Marie have tended to disprove rather than prove his claims that the pathology of the disease is found in atrophy of the cerebellum, the most striking changes having been found in the cord, in the shape of combined sclerosis very similar to that of Friedreich's disease. The author's own case was the second in the same family and presented, in addition to the signs said to be those of hereditary cerebellar ataxia, marked mental deterioration. Dr. Patrick thought that the whole group of cases including Friedreich's disease, the group selected by Marie and similar cases reported by others, should be considered as related to each other and dependent upon degeneration of several tracts, both afferent and efferent, having to do with the function of the cerebellum.

DR. SANGER BROWN agreed with Dr. Patrick in asserting that Marie was not warranted in making the statements that he did; still, in taking a broader view of the subject, and in accordance with the theory advanced by Dr. Barker, it was not a bad designation to refer to this disease as hereditary cerebellar ataxia. Marie was perhaps warranted in saying that in this disease the functions of the cerebellum were conspicuous'y

involved. Whether the incoördination means an involvement of the cerebellum, he did not know definitely, but that was the popular idea entertained by the profession. He thought there was a marked difference clinically between the series of cases that he reported and the series first reported by Friedreich, particularly as to the onset and progress of the disease, and that it was well to make a clinical distinction. There might be a variety of types of the disease in certain families; that is to say, certain parts of the central nervous system would show at a certain age defects, and he did not think the time had come when it was safe to classify these lesions under very hard and fast lines.

Referring to the remarks of Dr. Barker, it was well established that the functions of the cerebellum, judging from experiments upon animals, could be vicariously performed fairly well. If certain neurons connected with the cerebellum undergo injury or degeneration, if the disease was limited to particular neurons, or if the cerebellum was mainly at fault, the patients would not become progressively more and more ataxic. In the series of cases reported by the speaker, the patients became progressively more and more ataxic. They became somewhat weak, but if they could use other parts of the nervous system, they certainly had years to get over that particular defect, but they became steadily worse.

Regarding the case of Dr. Patrick, he agreed with him in many respects, although he was impressed with what James Collier and someone else stated in *Brain* some three or four years ago, in an elaborate report on diplegia, in which was reported a case similar to the one detailed by Dr. Patrick; only the cerebellum did not seem to be attacked so markedly in their case. He thought it could be classified with other cases, if it was assumed that the functions of the cerebellum were more markedly disordered, or that the degeneration extended to the cortex of the cerebellum as well as the cerebrum.

DR. SYDNEY KUH pointed out some slight discrepancies which exist between the results of experimental work as to the functions of the cerebellum and clinical experience. The results of experiments would seem to show that the tendon reflexes are exaggerated after injuries to the cerebellum. It was known from clinical experience that there is no localization of a lesion within the cranial cavity which is so frequently associated with loss of the deep reflexes as a cerebellar lesion.

As to the influence of the vermis, when he studied medicine he was taught that any part of the cerebellum might be destroyed without the manifestation of any symptoms, with the exception of the vermis. He had had occasion to examine the cerebellum of a patient who had been under the observation of Professor Vierordt and his assistant for physical diagnosis. The patient was an old man, who came complaining of violent pain, and upon examination they found a tumor of the liver. The patient's age and appearance justified a diagnosis of carcinoma of the liver. Patient was under observation and treatment for a long time. He was perfectly safe in stating that no such symptom as cerebellar ataxia or any gross nervous symptom could have been overlooked by these two gentlemen. The patient was treated with hypodermics of morphin. The case seemed absolutely hopeless, and nothing but symptomatic treatment was possible, and after one or two doses of morphin the patient became comatose, and died. Postmortem examination revealed, instead of carcinoma of the liver, secondary to a supposed carcinoma of the stomach, a large angiosarcoma of the liver. On opening the cranial cavity an angiosarcoma of the cerebellum was found. The tumor had destroyed practically everything of the vermis superior, the layer covering it being hardly any thicker than an ordinary card. It did not seem to the speaker that very much of the function of that portion of the nervous system was preserved. It is true, the tumor, as it appeared at the postmortem, was undoubtedly larger than it had been a short time before the patient's death, because death was largely due to hemorrhage into the tumor.

He was particularly pleased to hear what Dr. Barker had to say regarding the present classification of nervous diseases. Even if we knew nothing about the neurons, or the anatomy of the nervous system, clinical experience alone should have taught members of the profession long ago that there is no such thing as peripheral, spinal or cerebral disease, and in spite of

the anatomic researches extending back to the time when physicians hardly dreamed of a neuron that showed involvement of the nervous system in certain diseases, they are still classified in the same way.

DR. DANIEL R. BROWER said it was impossible to make fine distinctions between several forms of hereditary cerebellar ataxia. However, this was still being done by some neurologists. He reported at his clinic at the County Hospital a year ago a case that manifested certain symptoms suggestive of hereditary cerebellar ataxia, for the reason that the cerebellar connections were in some manner interfered with. It was not an ordinary case, inasmuch as the reflexes were so exaggerated, the eye symptoms pronounced, and the gait more like the gait attributed to cerebellar disease; therefore, he called the case one of cerebellar ataxia.

DR. ELBERT WING agreed with Dr. Barker in regard to the nomenclature of diseases. Physicians had been too exact in giving names to diseases, and in describing exactly the different pathologic locations. A classification such as Dr. Barker had alluded to was necessary in clinical work. The old classification would be gradually abandoned, as more definite knowledge was obtained.

DR. HUGH T. PATRICK said, in referring to the paper of Dr. Barker, that five or six years ago in writing an extended review of a monograph on hereditary cerebellar ataxia, he tried to express the same views that were presented by Dr. Barker, but did not do it so well, in that he tried to say, in all probability, the various diseases, including Friedreich's disease, were caused by progressive degenerative changes in nerve structures which were associated in function, and that the inception of the disease would vary in accordance with the particular set of neurons first involved. The clinical picture varied in accordance with the direction in which the disease progressed, and its extent. This was the conception which is taken now of a variety of cases including those in which the mental deterioration is considerable.

DR. BARKER stated, in connection with the progression of the symptoms in the cases suggested by Dr. Brown, beginning in youth, that the cerebellar disease ought to be compensated for largely by the vicarious activity of other parts. It must be assumed that disease is not stationary, and that, in all probability, group after group of neurons becomes involved, and those standing nearest in function and relation are most likely to assume vicarious function. He agreed with Dr. Wing in regard to attempting to localize or ascribe things exactly to one organ. On the other hand, he believes we will not be far wrong in attempting to localize diseases more exactly than we have heretofore by systems of neurons and conduction paths. An effort should be made in every case to correlate the clinical symptoms with changes in the neuron systems. If it is said that such and such neuron systems are involved, and such others are intact, then make careful autopsies and study the pathology from the same standpoint, and data would be accumulated which could not be obtained by present methods.

#### DETROIT MEDICAL SOCIETY.

Meeting held Wednesday, Dec. 4, 1902.

#### Ectopic Gestation.

DR. F. B. TIBBALS, in this paper, considered the etiology, classification and diagnosis of that condition, and reported four cases.

CASE 1.—Mrs. L., a young bride of but a few months, was first seen when suffering from a sudden attack of acute colicky pain in the right inguinal region. Bimanual examination negative. There was a history of menstrual irregularity with occasional passage of clots or decidua shreds. The attack subsided very quickly, but about ten days later recurred, and again a week later. At the third attack she was removed to Harper Hospital for an operation, which was made on the evening of August 5, 1899. She went on the table with a pulse under 90, showing that no dangerous hemorrhage was going on. Operation showed a pregnant right tube ruptured only enough to allow a slight hemorrhagic ooze. The patient made an ideal recovery.

CASE 2.—Mrs. C., married two years, thinks she miscarried a year and a half after marriage. The essayist was called on March 12, 1909, and found her in collapse from severe abdominal pain of very sudden onset. The shock was profound, although the pulse showed no hemorrhage. She had gone two weeks beyond her period, and considered herself pregnant. On March 22 Dr. Tibbals was again called in haste, to find a repetition of the former attack, plus a rapid pulse, showing internal hemorrhage. Within an hour she was operated on, the pulse being 140. The abdomen was filled with blood from a completely ruptured left tube, which was rapidly clamped and removed, the cavity cleaned out as thoroughly as was consistent with the condition of the patient, who had lost much blood. She was transfused, the colon filled with saline solution, and other means of stimulation freely used, and in a few hours she was out of danger. Recovery was uninterrupted. In the light of added experience the Doctor now feels that he should have diagnosed these cases positively at the first attack, by the typical symptoms alone, without waiting to confirm my suspicions by the actual feel of the enlarged tube.

CASE 3. Mrs. D., aged 35, one child of 7 years; when first seen on the afternoon of Feb. 22, 1901, she gave a history of menstrual irregularity since about Christmas time, and of two recent attacks of sudden shock and pain indicative of tubal rupture. A localized peritonitis existed with large infiltration on the right side of uterus, and a condition generally septic. She entered Harper Hospital that evening, it being evident that she would die from sepsis unless something could be done. On February 25 Dr. Tibbals opened the cul-de-sac, washed out a large quantity of foul broken-down blood, removed the right ovary and tube—the latter ruptured but not bleeding—and packed and drained thoroughly. After twenty-four hours, however, a general peritonitis developed, from which she died on March 2. This patient would doubtless have been saved by an early diagnosis and operation.

CASE 4.—Mrs. N., aged 35, married seventeen years, three children, one miscarriage four years before; consulted the essayist on April 13, saying that although her March period was on time she had continued to flow at intervals since. Examination disclosed no cause in the uterus for the irregularity of flow. He prescribed ergot and viburnum, and sent her to bed; she was not seen again until May 4, and then several times during the two weeks following. The flow continued at intervals, and in varying amount, never being entirely absent for more than a few days. She had no nausea, breast changes, pain or passage of decidua shreds, and did not believe herself pregnant, since her last intercourse was late in January, her February flow was normal, and her March flow was on time, though abnormal. The only diagnostic point of value was the irregular flow without apparent cause, until, within the last two weeks, he was able to detect an enlargement in the left pelvis, which he considered to be a tubal pregnancy, and urged operation, which he performed on May 24, at the Detroit Sanitarium. The left tube was found pregnant, unruptured, free of adhesions, and was quickly removed, and a happy optimistic prognosis concurred in by all present.

The personal equation of the patient, however, must always be considered in surgical work, and in this case clouds of gloom quickly hid the sunshine of egotistical pride in a good diagnosis and successful operation. The patient was an extremely nervous neurasthenic, and during her thirty-six hours of preparation in the hospital suffered much in anticipation of the coming operation. After one nearly sleepless night a violent thunderstorm during the evening before operation induced a sharp attack of fermentation in stomach and upper intestines, and she passed the night in great distress, belching gas in large amounts. The fear of rupture impelled the writer to go on with the plans for operation, but the pre-existing gaseous distension caused her death. The first two cases illustrate admirably the typical symptoms; the third case the hazard of delayed diagnosis; the last case the fortunate opportunity for diagnosis before rupture, as well as the uncertainties of surgery.

#### Meningitis Following Suppurative Otitis Media.

Dr. H. W. YATES reported the case of a girl aged 12, of good

physique and family history. In May of the present year she had a suppurative otitis media from which she apparently recovered. From this until Monday, last week, she was in good health. She complained then of slight earache on right side. On Tuesday the pain in the right ear had ceased, but the left one gave her trouble. This pain alternated between the right and left ears until Friday, when it was entirely relieved, only to be followed by an intense frontal headache. At this time I was called to see her. She had a temperature of 102, pulse 120; skin was dry and tongue coated. No appreciable change occurred in the pulse other than its frequency. The impression given at the bedside was one of the ordinary type of intestinal toxemia with its resultant cephalgia. The essayist prescribed one of the coal tar products for the relief of her headache and calomel as an eliminative. No more was heard from her until the following noon, Saturday, when he was called on account of severe headache. On arrival at 4 p. m. nothing more was discernible than on the previous day, with the exception that she laid with her eyes closed and apparently suffering intense pain, while her temperature had fallen to 101, and the pulse to 96. Owing to the severity of the pain, her unfavorable environment, coupled with suspicion of meningitis, he had her removed to the hospital. Her condition remained much the same until the following morning, when she developed slight paroxysms on one side, the central disturbance increasing until the left side became semi-paralyzed. The pulse now showed an appreciable change for the worse until she died, at 2 p. m.

On postmortem little was to be learned except that the pia mater was engorged apparently to its fullest extent, and there was considerable tension over the cerebral hemispheres. No abscess could be found, but with the highly injected condition of the pia mater it was concluded that an infective leptomeningitis was the cause of the fatality.

This case shows none of the classical symptoms of meningitis, such as chill, fever, hyperesthetic skin, muscular spasm, disturbances of the special centers, ptosis, strabismus, irregularly contracted pupils, or Cheyne-Stokes respirations; yet with the forerunning history of otitis media in the early spring, together with the initial pain in the ears during her fatal illness, it would seem that an abscess of the middle ear had been provocative of the fatal result.

#### NEW YORK ACADEMY OF MEDICINE.

Meeting held January 2, 1902.

Vice-President Dr. Charles L. Dana, in the Chair.

#### The Need of Sanatoria for Tuberculosis.

DR. G. L. PEABODY, in the opening paper on this subject, called attention to the greater advances along this line that had been made in Europe, and said that it had been estimated that 75 per cent. of the cases of tuberculosis that had been restored to health had been through the medium of sanatoria. All agreed that life in the open air was essential, and that a climate was required in which there were not sudden and great changes of temperature. Alcohol and changeable weather were powerful factors predisposing to tuberculosis.

DR. S. A. KNOPF said that the statistics of the last fifty years seemed to indicate that tuberculosis had decreased about one-third, and this, he declared, had been largely brought about by sanatorium treatment. Touching upon the recent effort to exclude from this country all tuberculous immigrants, the speaker said that if we were going to exclude all consumptives coming here from other countries, these nations might retaliate. Dr. Knopf then introduced the following resolutions, which, under the rules, could not be acted upon until the next meeting of the Academy:

WHEREAS, The Treasury Department of the United States, upon recommendation of the Surgeon-General of the Marine-Hospital Service, has recently decided to classify tuberculosis as a dangerous contagious disease, thereby placing a stigma wholly undeserved upon every American citizen who is suffering with consumption, be it

*Resolved*, That the Academy considers the exclusion of non-pauper tuberculous immigrants and tuberculous aliens visiting our shores, unwise, inhumane and contrary to the spirit of American justice; and, be it further

*Resolved*, That while the Academy upholds the fact of the communicability of tuberculosis, and urges all possible precautions

against the spread of the disease from sputum and other tuberculous secretions or from ingestion of tuberculous food substances, the Academy is opposed to all measures by which additional hardship is imposed upon the consumptive individual, his family or his physician.

Dr. HENRY P. LOOMIS graphically described the pitiable wanderings of the poor consumptives from one hospital to the other, and declared that what the city needed at once was a large hospital where all the consumptives could go as soon as they needed hospital care, and where they might receive systematic and continual oversight. He believed that, even in such a hospital, the number of cured cases would be a surprise. On economic grounds the taxpayers should demand such an institution, and the profession should see to it that a public sentiment was created which would make the opening of such a hospital imperative. Fortunately, the city would not have to wait even for the erection of a building, for at present there stands empty, on Ward's Island, a city hospital capable of accommodating 400 patients. Dr. Loomis estimated that there were between 20,000 and 25,000 cases of tuberculosis in New York City. Out of the 427 medical cases admitted to Bellevue Hospital in December, 138 were cases of tuberculosis, or about one in three.

Dr. J. EDWARD STUBBERT, Liberty, N. Y., spoke of the advantages of sanatorium treatment, not only in the way of diagnosis and treatment, but as a means of educating the patients so that they became teachers of hygiene on returning to their former homes. Speaking of the chances of recovery, he significantly divided cases of tuberculosis into two classes, the careful and the careless.

Dr. W. FREUDENFELD favored the purchase of tracts of farm land and the establishment of tent colonies. Under such conditions the disease was most apt to be arrested, and by giving the patients work on the farm they were kept occupied and contented, and did not find it necessary when half cured to go back to live and work in crowded cities.

Dr. E. H. M. SELL insisted that tuberculous patients, after the arrest of the disease, should continue to live in the climate in which they had been restored to health.

Dr. E. G. JANEWAY thought that those who had observed the wonderful beneficial influence of a suitable climate upon tuberculous patients would be loath to argue in favor of the treatment of consumption in the city. Sanatoria might be established in the country for incipient cases, and hospitals provided in the cities for more advanced cases of the disease.

Drs. Leonard Weber, Alfred Meyer and Louis Faugères Bishop spoke in favor of the establishment by the city or State of sanatoria for consumptives, and Dr. A. Jacobi pointed out the utter brutality of telling a poor consumptive, who was unable to procure needful food and comforts, that it was absolutely necessary for him to go to Colorado if he would be cured.

#### PHILADELPHIA COUNTY MEDICAL SOCIETY.

*Meeting held Dec. 18, 1901.*

Dr. Geo. Erety Shoemaker, in the Chair.

#### The Shock of Intra-Abdominal Operations, Its Pathology, Prevention and Treatment.

Dr. LOUIS S. McMURTRY, Louisville, Ky., defined shock as a neurosis resulting in an inhibition of the vital functions, affecting especially the vasomotor system. As to causation of shock, prolonged and extensive exposure and rude manipulation of organs, and hemorrhage, were cited as predominant factors. The importance of special prophylactic treatment of a weak patient was emphasized—such treatment to include active feeding with bland nutritious liquid, administration of strychnia, and enteroclysis of saline solution. Careful anesthetization with ether, careful maintenance of bodily heat, prompt arrest of all hemorrhage, the shortest abdominal incision, and the least and gentlest manipulation practicable, quick and dextrous operation, were all urged.

Dr. JOSEPH PRICE compared some of the results of the early operators with those of the later surgeons.

Dr. JNO. G. CLARK referred to the conclusion reached by Hodges, in his investigations, that in serious shock the vasomotor nerves undergo pathological changes, but temporary, if

reaction occurs. Clark believes the toxic effect of the anesthetic often to be a strong causative factor of shock.

Dr. DEFOREST WILLARD made a plea for better guarding the patient from loss of heat upon the operating table. He believes the electric mattress useful for this purpose.

Dr. JNO. B. DEEVER pointed out that patients frequently suffer shock because of delay of operative interference and sepsis depressing the vital powers before operation. He therefore strongly urges early interference in cases demanding operation. In treating shock, he depends much upon camphorated oil, atropia and intravenous injection of saline solution.

Dr. EDWARD MARTIN referred to tests he had made to determine the quantity of blood-loss in operation. By weighing the sponges, he determined that the quantity of blood lost is often underestimated. He also believes that Crile's experiments suggest the probability of cocaine being a preventive of shock, and that atropia and strychnia are distinctly serviceable. Deaths that he has seen have been from respiratory failure, hence the value of artificial respiration. He believes that the intravenous injection of saline solution sometimes causes congestion because of the sudden great increase of circulating fluid, while hypodermoclysis—the fluid being drunk up as the tissues need it—is invaluable.

Dr. ERNEST LAPLACE defined shock as a "depression, because of an impression." The speaker pointed out that in operative or other traumatic shock there is accompanying anemia of the brain, with the notable exception that in direct injury of the brain itself there is cerebral congestion with full bounding pulse.

Following the meeting, an informal reception to Dr. McMurry was given at the University Club.

At the same meeting a resolution was adopted strongly disapproving, as a Municipal Hospital site, of a plat of ground on the Delaware River front, which Councils have under consideration. The place is difficult of access, the ground marshy, in proximity to fertilizing factories, and most unsanitary. The resolution provided also for a committee of five to inspect sites proposed for the Municipal Hospital and to report to the Society regarding their fitness.

## Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

### PRESCRIPTION WRITING, IX.

*(Continued from page 126.)*

#### Pharmaceutical Incompatibility (Continued).

As a rule water is the best solvent for gelatinous, gummy and saccharin bodies and for a great number of inorganic salts; but all drugs containing the volatile oils and resins, gum resins, resinoids and balsams as their active principles, are best dissolved in alcohol. It might be well to add that the solvent power of either alcohol or water decreases in direct proportion to the amount of the other added.

Glycerin makes a good solvent for bodies which are soluble in both alcohol and water, and may be in some cases more preferable than alcohol. It is regarded as a superb solvent for sodium borate, boric acid, tannic acid, gallic acid, creosote, bismuth subnitrate, amyllum and iodine.

As stated by Scoville, there are methods which may be employed to remedy or prevent some of the physical incompatibilities that might otherwise arise, but as these come in the rôle of the pharmacist they need be only enumerated in summing up the foregoing statements:

1. By order of mixing.
2. By keeping the alcoholic strength within certain limits.
3. By using different solvents.
4. By suspending in emulsions.
5. Remembering that the three great solvents are water, alcohol and glycerin in the order mentioned.

The following prescriptions illustrate pharmaceutical incompatibilities resulting from certain combinations:

R. Tinct. benzoini comp.  
Tinct. cardamomi comp.,  $\mathfrak{A}\mathfrak{A}$   $\mathfrak{Z}\mathfrak{i}$  30  
M. Sig.: One teaspoonful after each meal.

The tinctura benzoini composita is made from a strong alcoholic menstruum while the cardamon preparation is made from a dilute alcoholic solution; consequently the resin in the first preparation would be precipitated.

R. Oleoresine eubear  $\mathfrak{Z}\mathfrak{ii}$  7|50  
Aque  $\mathfrak{Z}\mathfrak{ii}$  60  
M. Sig.: One teaspoonful after each meal, in water.

The oleoresin of course is insoluble in water, so that this prescription would be incompatible. In this case suspension of the oleoresin in an emulsion by adding one or two drams of aëcia to the above would correct the incompatibility.

R. Tinct. gentiane comp.  $\mathfrak{Z}\mathfrak{i}$  60  
Syrupi simplicis  $\mathfrak{Z}\mathfrak{ii}$  60  
M. Sig.: One teaspoonful three times a day.

As has been already stated the compound tincture of gentian, which is made from stronger alcohol, will cause the sugar to crystallize.

R. Olei juniperi  $\mathfrak{Z}\mathfrak{i}$  3|75  
Aq. menthe pip. q. s. ad  $\mathfrak{Z}\mathfrak{iii}$  90  
M. Sig.: One teaspoonful four times a day.

In the foregoing prescription the oil in the juniper would be thrown out of solution and rise to the top of the mixture, because of the vehicle used.

R. Extracti grindelie rob. flu.  $\mathfrak{Z}\mathfrak{i}$  30  
Aq. destil. q. s. ad  $\mathfrak{Z}\mathfrak{ii}$  60  
M. Sig.: One teaspoonful three times a day.

The resinous principle would be thrown out of solution on account of the water weakening the alcoholic fluid extract of grindelia.

R. Potassii iodidi  $\mathfrak{Z}\mathfrak{i}$  30  
Aque mentha viridis  $\mathfrak{Z}\mathfrak{i}$  30  
M. Sig.: Take ten drops after each meal and increase one drop every other day.

In this case the aqua menthae is a saturated solution of the oil, so by saturating it with the potassium iodid salt, which is very soluble, the oil would be thrown out of solution and cause the mixture to become cloudy.

R. Magnesii sulphatis  $\mathfrak{Z}\mathfrak{i}$  30  
Ext. taraxaci flu.  $\mathfrak{Z}\mathfrak{i}$  30  
Aque q. s. ad  $\mathfrak{Z}\mathfrak{iv}$  120  
M. Sig.: One or two teaspoonfuls upon rising in the morning.

The soluble magnesium sulphate would in this case be precipitated by the alcoholic fluid extract in the mixture and the resins in the fluid extract would be precipitated, demonstrating the law that the more soluble a body is in water the less so in alcohol, and vice versa.

R. Chloralis hydratis  $\mathfrak{Z}\mathfrak{ii}$  7|50  
Camphore gr.  $\mathfrak{x}\mathfrak{iv}$  1|65  
M. Sig.: One powder at bedtime.

By triturating these preparations together they would liquefy and consequently powders could not be made.

Attention has been called to a prescription upon a druggist's file which contained the following physical incompatibilities:

R. Ext. leptandrie flu.  $\mathfrak{Z}\mathfrak{v}$  18|75  
Ext. cannabis indicæ flu.  $\mathfrak{Z}\mathfrak{ss}$  1|88  
Ext. ergotæ flu.  $\mathfrak{Z}\mathfrak{iv}$  14  
Syr. lactuæarii  $\mathfrak{Z}\mathfrak{ss}$  15  
Aq. destil. q. s. ad  $\mathfrak{Z}\mathfrak{iii}$  90  
M. Sig.: One teaspoonful four times a day.

In the above the resinous principles of the first two fluid extracts would be precipitated by the water given as the vehicle.

(To be continued.)

### Atropin in Acute Pulmonary Edema.

Acute pulmonary edema demands very prompt and vigorous measures for its relief. Dr. C. Donovan, in *Amer. Med.*, recom-

mends strychnin gr. 1/50 with atropin gr. 1/100 to be injected beneath the skin just below the clavicle, in order that it may reach the heart sooner. The evidences of good results thus obtained are shown by the skin becoming moist and warm, the breathing deeper and less frequent, and the suffocation relieved. If the pulse shows indications of good strength, one injection will be enough; otherwise he recommends additional doses of strychnin to stimulate the heart.

Where high arterial tension is present and the heart's action strong the atropin may be given in combination with nitroglycerin and morphin. He states that the atropin should show its effects physiologically upon the pupil of the eye. He usually begins with gr. 1/100 and repeats the dose at intervals of one hour until the desired results are obtained.

### Treatment of Carbuncles.

Wm. Wormley, in *New York Med. Times*, recommends the use of tonics such as iron, arsenic and quinin. The following prescriptions are employed by him very frequently:

R. Potassii iodidi  $\mathfrak{Z}\mathfrak{ss}$  1|88  
Ferri pyrophosphatis  $\mathfrak{Z}\mathfrak{i}$  3|75  
Syrupi  
Aque,  $\mathfrak{A}\mathfrak{A}$   $\mathfrak{Z}\mathfrak{ii}$  60  
M. Sig.: One teaspoonful diluted in water after meals.

Gross, according to his statement, recommends the following as a cover for the carbuncle, first painting it with tincture of iodin:

R. Olei terebinthinæ  
Olei olivæ  
Tinct. opii,  $\mathfrak{A}\mathfrak{A}$   $\mathfrak{Z}\mathfrak{ss}$  15  
M. Sig.: Apply locally.

The foregoing is regarded as an antiseptic, destroying the cocci if they are not too firmly established in their location. The following is sometimes used:

R. Tinct. arnicæ flor.  $\mathfrak{Z}\mathfrak{i}$  3|75  
Acidi tannici  
Pul. acacie,  $\mathfrak{A}\mathfrak{A}$   $\mathfrak{Z}\mathfrak{ss}$  1|88  
M. Sig.: Paint over the carbuncle every fifteen minutes until a thick coat is formed.

### Salicylates as Antiseptics in Pneumonia.

Sebring, as noted in *Prog. Med.*, states that he treated a series of seventy-five cases of pneumonia with but one death. He administered 120 grains of the salicylates daily as a routine treatment.

### Pruritus and Fissures of the Anus.

Dr. W. C. Black, according to *Merck's Archives*, states that the following treatment is successful in severe cases of pruritus ani, especially those complicated with fissures. The sphincter ani is stretched until there is complete relaxation, and the mucous membrane within the sphincter is painted with the following:

R. Ichthyol  
Glycerini,  $\mathfrak{A}\mathfrak{A}$   $\mathfrak{Z}\mathfrak{i}$  31|1  
M. Sig.: Apply locally.

He states that this treatment has proved in his hands more successful than any other remedy or method that has ever been recommended. Recently he has had good success with ichthyol injected in full strength, just within the sphincter, twice or three times a day.

## Medicolegal.

**Unpatentable Devices for Treatment of Disease.**—A patent can not be lawfully granted, the United States Circuit Court of Appeals holds, in the case of *Mahler vs. the Anmarium Company*, when it appears that the claim preferred by the patentee that he has made a discovery of a new fact or principle in medical science, and of a new mode of operation of a known force whereby the discovery is utilized, rests upon no substantial foundation, and is at best an imaginary hypothesis, and was most likely put forward merely to obtain a patent on a device which he proposes to make and sell to the public for the treatment of disease. The granting of a patent under such

circumstances, the court declares, would give to the theories enunciated in the specification an appearance of authority, and tend to mislead and deceive the public if the theories are false.

**Exhumation and Autopsy Months After Death.**—Complaint was made in *Hayes vs. State of Wisconsin*, a homicide case, of the admission of the testimony of a physician as to the result of a postmortem examination made by him of the remains of the deceased some months after death, without notice to the accused. But the Supreme Court of Wisconsin says that it knows of no law that requires notice to the accused in such cases. The disinterment and examination was under the direction of the proper authorities, and in furtherance of public justice. The statute against disinterments was not intended to apply to exhumations made by public officials with a view of ascertaining whether a crime has been committed. The objection that the evidence was inadmissible because of the length of time that had elapsed went rather to its weight than its competency. The doctor testified that the body was not so far decomposed but that he was able to discover knife wounds in the back, and the presence of blood in great quantity in the chest cavity. It was for the jury to determine whether the proof was of sufficient weight to satisfy legal requirements.

**Injury Followed by Quick Consumption.**—In the case of *Hoey vs. the Metropolitan Street Railway Company*, Mr. Justice Russell holds, at a trial term of the Supreme Court of New York, that a jury having found that tuberculosis caused a person's death, the bare possibility that his frame, weakened by an injury sustained nine or ten months previously, succumbed more readily to the new disease, was insufficient upon which to rest a finding to the effect that he would not have died at the time he did but for the injury, or that the latter was the cause of his death. True, aid was afforded to the jury and the court to link the accident to the death by the opinions of eminent physicians upon the assumed facts that a disease called "progressive muscular atrophy" caused the death by shattering the system, and thus exposing it to sudden disease. But all of the physicians substantially agreed that tuberculosis was produced in the lungs by the inhalation of the germs from the atmosphere, and, accepting this view, it is said that it must be regarded as a conclusive fact that the man died from consumption immediately produced from the inhalation of bacilli, and not produced by a blow over nine months before his death.

**Privilege Under North Carolina Law.**—The Supreme Court of North Carolina says, in *Fuller vs. Knights of Pythias*, that at common law there is no privilege extending to the relation between patient and physician. The privilege between patient and physician created by the North Carolina statute of 1885 is less stringent and more lax than that of the common law between attorney and client. As between the latter, the attorney's mouth is sealed for all time (except by consent of the client), and he can not be compelled by the court to testify; while under the statute referred to it is provided that the judge, in furtherance of the administration of justice, may compel the physician to disclose the information acquired by him from his patient. The language of the statute is, "No person duly authorized to practice physic or surgery shall be required to disclose any information which he may have acquired in attending a patient in a professional character, and which information was necessary to enable him to prescribe for such patient as a physician, or to do any act for him as a surgeon: provided that the presiding judge of a superior court may compel such disclosure if in his opinion the same is necessary to a proper administration of justice." Under these circumstances, the Supreme Court holds that a waiver in an application for life insurance was good and binding upon the beneficiary, and that the judge of the Superior Court erred, in this case, in excluding the testimony of the physician as to knowledge and information acquired from the deceased, who had made the waiver, while attending him professionally.

**Court Can Not Supplant Board of Medical Examiners.**—In the case of *State ex rel. State Board of Medical Examiners vs. First Judicial District Court of Montana*, it appeared that

an applicant for a certificate to practice medicine was detected in the use, during his examination, of certain notes and memoranda to aid him in answering the questions propounded, and was thereupon denied the privilege of continuing the examination. A charge was preferred to the board by its secretary, accusing him of "unprofessional, dishonorable, and immoral conduct," the specification being that he had been detected in the use of said notes and memoranda for the purpose stated. After written notice, and an examination by the board into the facts, he was found guilty, and refused a certificate. He immediately appealed to the District Court, and thereupon applied to it for an order permitting him to engage in the practice of his profession until a hearing could be had upon the merits, and the judge, after requiring him to submit to an examination in open court as to his qualifications, made such an order. Was this within the power of the court? The legislature of the state has deemed it proper, in a case where a certificate has been revoked, to authorize the courts, in their discretion, to grant the appellant permission to practice pending his appeal, but it is silent as to the power of the court in cases in which the board has refused a certificate. Under these circumstances, the Supreme Court of Montana holds that it was not within the power of the District Court to make the order mentioned. It says that the prohibition directed to the individual citizen against practicing medicine until he has been examined by the lawfully constituted authorities and declared sufficiently qualified is as much a limit to the power of the court as if it had been expressly provided that the court should not grant permission to pursue the practice pending appeal in this class of cases. It sees a difference, too, in granting the right to practice medicine pending an appeal between such a case as the legislature has provided for and that here under consideration. In the former, it says, the conditions precedent have all been fulfilled. The party's right has accrued. He has, perhaps, by his energy and application, built up a profitable practice. It is the means of support for himself and family. This should not be taken away without good cause. It is, therefore, but just that he be permitted to exercise his right until it is finally adjudged that he has forfeited it; especially so, if it is made to appear that the forfeiture has been declared upon doubtful evidence, or from bad motives on the part of the board. But in the case of an applicant for a certificate in the first instance no such reason exists. No right has been established. No practice depends upon his attention. He will suffer no immediate material injury if the certificate be withheld for a reasonable time until he can demonstrate that the action of the board in denying it was arbitrary or erroneous. The burden is upon him to establish his right. In the other case the burden rests upon the state represented by the medical board.

## AMERICAN.

1. **Hodgkin's Disease.**—The conclusions of Musser's article are that Hodgkin's disease is in all probability a lymphatic tuberculosis. Fever, recurrent in type, occurs commonly in this affection of the glandular structures. So-called recurrent fever is a symptom, not a disease. In a few rare instances the clinical diagnosis, when such fever prevailed, was malignant lymphoma (Pel), sarcoma (Völckers), myelosarcoma (Hammer), and lymphosarcoma (Remus and Witthower, Seeborn). It must be remembered that such distinguished authorities as Ehrlich and Lazarus believe that Hodgkin's disease is a lymphosarcoma, and that the tuberculous process is accidental. Sternberg, on the other hand, has pointed out the differences, and insists strongly upon the tuberculous as the process giving rise to the adenitis of Hodgkin's disease. He believes that the symptoms are different from those of other forms of tuberculosis, the anatomy of the gland having much to do with the process. He agrees with the conclusions of Sternberg.

2. **Bovine Tuberculosis.**—De Schweinitz and Schroeder have experimented on several baboons and monkeys as to their susceptibility to bovine tuberculosis and give the details. In all the cases there was a disseminated tuberculosis, the most marked in the higher monkeys. The animals succumbed usually within a few weeks at the outside and mostly within less than two months. The evidence shows a greater, rather than decreased, vulnerability to bovine tuberculosis for animals nearest related to the human species, and consequently by inference to man. They have also tested on various animals the effects of tuberculin made from bovine cultures, following the same rules as were made for human cultures as well as tuberculin made from swine and avian tuberculin. The tubercle

germ from the horse produced no reaction, which was accounted for possibly by the fact that the disease in the animal tested had been arrested.

4. **Hypnotism.**—From an analysis of the subject, so far as can be made, Burr comes to the conclusion that hypnotism is absolutely of no value in organic diseases. In functional ones its effect is little more than that of suggestion, which is an entirely different thing and has always been in use by medical men and others. Hypnotism is the mere garment in which for the time being suggestion has been clothed and is for the most part unnecessary in carrying out suggestive therapeutics as regards its usefulness. In education it has been tried and found wanting. Hypnotism injures the young, but suggestion is the tool of every wise schoolmaster.

5. See abstract in THE JOURNAL, xxxvii, p. 934.

9. **Czolgosz Case.**—MacDonald's paper reviews the history of the assassin of President McKinley and gives the details of his personal examination of the assassin. He seems to suspect at least that Czolgosz had associates in the anarchical societies to which he belonged and was appointed to do the act. Reviewing the case in all its aspects he records his opinion expressly that Leon Czolgosz on Sept. 6, 1901, was in all respects sane both legally and mentally and fully responsible for his acts.

10. **The Czolgosz Postmortem.**—The details of the post-mortem of Czolgosz, together with illustrations of the head casts taken after death and of the convolutions of the brain, etc., are detailed by Spitzka, who believes that from pathologic evidence the victim must have been socially diseased and perverted, but not mentally diseased.

12. **Rupture of the Spinal Ligaments.**—Painter and Os-good report four cases of injury to the spine in which there was kyphosis without tuberculosis or other disease of the vertebra and in which there were symptoms of pressure upon the cord that were relieved. The patients entirely recovered after a few months' treatment with plaster or other jackets. He has also collected 15 cases which seem to him to be uncomplicated rupture of the spinal ligaments and of which he gives a brief description. The following conclusions he thinks are justifiable: "1. Spinal ligaments, during life, may be ruptured without fracture or dislocation. 2. Nerve pressure symptoms may occur from a simple flexion of the vertebral column. 3. Recovery in these cases requires prolonged rest in a position which favors the repair of ligaments, and that the effects of treatment speaks more for the ligamentous rupture than for luxation of fracture. 4. The force that commonly produced the injuries (when stated) was one which, *a priori*, would be most likely to produce ligamentous rupture."

13. **Placenta Previa.**—The mortality from placenta previa, according to Higgins, is not now over 10 per cent.; generally under favorable circumstances and in skillful hands it is below 5 per cent. Abdominal section, he maintains, is hardly ever indicated and does not hold out even in favorable cases the promise of better than 10 per cent. mortality. Its risks are much greater and in unfavorable circumstances its mortality is prohibitive. The only cases of placenta previa in which Cesarean section is justified in his opinion are those at full term with complete previa, a rigid os, seen before the occurrence of any severe or dangerous hemorrhage, and with the mother and the fetus in good condition. He does not think that the prognosis of the child in Cesarean section is usually as good as estimated, and he thinks the reason why they seem less vigorous than those of the natural born is due to something more than etherization. In 25 Cesarean sections which he has seen, it was exceptional that the child did not cause more anxiety at the time of operation than the mother or that it did not have to be resuscitated with great care and by prolonged immersion in hot water.

14. **Privileged Communications.**—The views held by Nichols and derived from considerable experience in courts is that the exceptional admission of medical evidence that might be considered privileged has been favorable to the best administration of justice. He does not apparently favor the New

York law, and thinks that any amendments to our present rules of evidence are needless. The whole matter of privileged testimony, he thinks, can be safely left to the discretion of the presiding judge, with the understanding that in the interest of public morality it would be a distinct advantage if evidence affecting the honor or social position of individuals or families could be given in private before a referee (?).

15. **Traumatic Asphyxia.**—Burrell and Crandon report a case and discuss the subject. They call particular attention to the skin symptoms and remark that the diagnosis ought not to be difficult if the person is still living. The victim of overcrowding, besides his contusions and possibly broken ribs and sternum, presents the localized bluish coloration as described, which is to be distinguished from cyanosis, is stupid up to insensibility, and has no delirium, no convulsion, no paralysis. The treatment should be immediate, as soon as the patient is seen, by artificial respiration, as in cases of drowning, if the patient is suffering from mechanical suppression of the phenomena of respiration.

16. **First Aid in Railroad Wrecks.**—Lofton advises the drilling of train hands in the art of rendering first aid. This should be done by the chief surgeon of the railroad and his assistants. Every train should have its first-aid surgical chest, containing material for stopping hemorrhages, stimulation, etc. The employees should be taught to know when and how to stimulate patients, judging from their pulse rate and appearance. They should be taught the great necessity for relieving pain and placing the wounded in the most favorable and comfortable position looking towards reaction. If this was done scientifically he believes the mortality in railroad wrecks would be lessened 85 per cent. Shock is the ordinary cause of death, but hemorrhage will account for it, he holds, in 90 per cent. of the cases; hence, the importance of education to meet this condition.

19. **Round Ligament Ventrosuspension.**—Gilliam has modified his operation as it was first performed so as to simplify the technique and improve its efficiency. The operation is as follows: "An abdominal incision three or four inches in length is made in the median line at the usual site between the umbilicus and pubes. The adhesions are broken up and the fundus brought forward. With a finger and thumb or a pair of bullet forceps the broad ligament of one side is seized and brought to the opening. By lifting up the anterior surface of the broad ligament on the tip of a finger applied to its posterior surface the round ligament is brought into view and is picked up, either between the thumb and finger or with a bullet forceps. Selecting a point an inch and a half from the uterus, a thread is passed under the round ligament and the ends of the thread are brought out of the opening and secured in the bite of a clamp forceps, which is laid upon the surface of the abdomen. The other ligament is sought for and secured in the same manner. At a point about one inch and a half above the pubes, the peritoneum, muscle, and fascia at one edge of the wound are caught up by a volsella and pinned together, being careful that the edges of these layers are in line. Traction is now made, and, with a small retractor, the skin and superficial fat are drawn in the opposite direction, uncovering the fascia. With a narrow-bladed knife, or better with the perforating forceps devised for the purpose, a stab wound is made from the surface of the fascia into the peritoneal cavity, the instrument entering one-half inch from the edge of the abdominal incision, and passing obliquely downward and outward, emerging on the peritoneum one inch from the edge of the abdominal incision. If the perforating forceps is used, the jaws are separated, and, by an outward movement of the handle, brought into plain view at the large opening. The thread which loops the round ligament is now placed in the jaws, the clamp forceps removed, and the perforating forceps withdrawn, bringing with it the thread and the ligament. If a knife has been used to make the perforation, it is withdrawn and a slender forceps introduced, with which the thread is caught up and the ligament drawn into place. Now, while the ligament is held taut, with its loop end a quarter or third of an inch above the

surface of the fascia, a catgut suture is passed through it, including the tissues on either side, and back again, where it is tied. This is cut close to the knot, the suspending thread cut on one side close to the ligament and withdrawn, and the volsella and retractor removed. The other side is dealt with in like manner and the abdominal incision closed." He claims that this leaves ample space for uterine pregnancy and also obviates any possibility of strangulation of the bowel. The uterus rests easily and naturally on the bladder from which it can be raised to a position little short of vertical. In his later operations he has had no trouble whatever from suppuration, which he attributes to the fact that he handles the ligament as little as possible and clips the suspending thread close to the ligament so as to avoid contamination by drawing it full length through the loop of the ligament after exposure of the abdominal wall. The slanting perforation of the abdominal wall through which the ligament is drawn is made in deference to a suggestion of Dr. W. E. B. Davis, who thinks it would be a safeguard against hernia.

21.—See also ¶9.

22.—Ibid., ¶10.

23. **Yellow Fever.**—This article is called out apparently by a letter from Dr. John H. Purnell, published in the *Philadelphia Medical Journal* of October 19, 1901. Gorgas gives the history of the yellow fever occurring in Havana, showing that by the methods adopted of screening the houses where yellow fever occurred and killing the mosquitoes, the foci were stamped out without any regard to the question of fomites whatever. He says that the death rate has fallen in Havana from 91.03 in 1898 to 24.40 in 1900, and probably to 21 for 1901. The methods employed involve a certain amount of expense, but he thinks the benefits obtained justify it. He considers that the facts as he gives them are strong enough proof of the theory of the mosquito-borne nature of yellow fever infection.

24. **Rheumatic Fever.**—Duckworth's article is a clinical lecture based on a case of blood poisoning in a boy with rheumatic symptoms. He discusses the diagnosis of rheumatic fever, holding that all the forms of arthritis or joint disease are the result of some infection, with one exception, gout. This seems to be the only exception in so far as the noxious matter does not come from without but from within. The gouty patient makes his own poison; the rheumatic patient receives toxins from other sources. What are these toxins? He mentions here influenza, gonorrhea, cerebro-spinal meningitis, osteomyelitis setting free staphylococcal and streptococcal infection. He says whenever we find salicylates ineffective we may reasonably conclude to revise our diagnosis and see if we are dealing with a case possibly not of rheumatic fever, but with arthritis due to some other infection.

25.—See also ¶9 above.

26.—Ibid., ¶10 above.

27. **Sanitary Aspects of the Panama and Nicaragua Canals.**—The climate, topography, etc., of the Panama and Nicaragua routes have been studied by Soper, who comes to the following conclusions: Both pass through a country which is extremely unfavorable to health. The difference between the Nicaragua and Panama is chiefly in regard to rainfall, that of Panama being most favorable to health. The soil condition, topography and engineering work are in favor of Panama; fewer men would be required and could be better protected. There is practically no difference in the nature of the diseases to be expected or in the nature of the precautions required. After construction the difficulty of controlling health conditions along the line would be greater on the Nicaragua route. The shorter Panama route would cause passing vessels to be less exposed to infection and the likelihood of the canal becoming a disease focus is much greater of Nicaragua than of Panama. Although there has been great loss of life by disease in the latter, this must not be considered as evidence of the greater immunity of the Nicaragua route. It is simply due to the greater number of persons exposed. Whichever route is selected extraordinary care will be required to maintain satis-

factory health conditions during construction and after completion of the work. The plans and preparations in detail for an efficient sanitary and medical department should be made as early as possible.

28.—See also ¶9 above.

29.—Ibid., ¶10 above.

30. **Suprarenal Extract.**—Forty-five cases of the use of suprarenal extract, for hemorrhage, 21 of hemoptysis, 23 of uterine hemorrhage, and one of hematemesis, are reported, in all of which suprarenal powder was used internally. The application was generally by 5 gr. placed on the tongue, thoroughly rinsed with saliva and swallowed without water, which usually produced an effect within ten minutes. Nausea and vomiting were observed in only a few cases. The author knows of no other remedy internally administered which has given him such prompt results. It has proven a safe remedy even when the hemorrhage was complicated by disease of the heart, lungs, and kidneys.

31. **Hysterical Hemiplegia.**—A case is reported in detail by Winter, who discusses its pathology and gives his theory that paralysis was brought about, not by disease of the nerve processes, but by a retraction of the terminal end-brushes of the sensori-motor (psycho-motor) neurons, thus preventing the impulse from reaching the distinctly motor neurons. The etiologic factors were an inherited predisposition or mental instability, shock at the age of 9 years, increasing instability and keeping the fear of paralysis constantly before the patient, by suggestion from his family and himself, thus making suggestion the real exciting cause. Counter-suggestion, therefore, was adopted, and it proved successful. He thinks that one reason why so many frauds exist like Eddyism and Dowieism, etc., is the important and woefully neglected by the profession element of suggestibility.

32. **Absorption of Alexins.**—In this brief preliminary conclusion Levene alludes to the fact that different investigators have shown that the bacteriolytic or hemolytic sera when digested with dead bacteria of the different species lose their bacteriolytic power over other bacteria and also their hemolytic power. If, instead of dead germs, bacteria previously treated with a bactericidal serum heated at 55 C. be allowed to act on a bacteriolytic or hemolytic serum, the latter will lose its power to dissolve other bacteria or red cells. On the other hand, living bacteria fail to produce any effect on a normal serum which has no bactericidal power over the same bacteria. Thus it would appear that dead bacteria possess the power of absorbing alexins from normal sera, while living bacteria do the same only after having been previously saturated with the "immune body." He has experimented thus far only on the reaction of rabbits' serum to tubercle bacilli, to find out: 1, whether the normal sera lose their hemolytic power on digestion with dead tubercle bacilli; 2, what the power of a given serum should be if treated with living bacilli; 3, if an animal should be found whose serum normally does not lose its hemolytic power on treatment with living bacilli, would the serum of tuberculous animals act differently? As a result of his experiments he finds: 1. There exists a certain minimum quantity of dead tubercle bacilli, which it is necessary to add to a given serum in order to deprive it of its hemolytic power. Smaller quantities only diminish, not wholly abolish this. 2. Living virulent bacilli added in quantities approximately equal to the minimum of the dead bacilli have scarcely any effect on the hemolytic power of the serum. Added in larger quantities they diminish the hemolytic power of a serum, but in lesser degree than do dead bacilli. Further he finds that the "attenuated" cultures act in the same manner as the dead germs. When the serum of animals previously treated with the extract of crushed tubercle bacilli is tested with living virulent bacilli it loses its hemolytic power much more rapidly than does a normal serum. He is further investigating along this line.

33. **Refraction Errors.**—Buckner advocates the ideas advanced by Stevens, Ranney and others as regards the importance of refraction errors in the production of cerebral and other symptoms and reports three cases of neuralgia which were

relieved by the correction of such errors. In one case there was a mixed origin admitted. In the other cases he claims that his diagnosis was correct and the result of operation was relief.

**42. Pseudo Appendicitis in Children.**—Fischer calls attention to a class of cases in children where the symptoms so strongly resemble appendicitis that operation will be proposed and yet the condition be different. Two cases are reported, one of catarrhal gastritis and the other of peritonitis from traumatism though the symptoms strongly suggested appendicitis. When the diagnosis is made by the process of exclusion great care should be exercised before resorting to extreme measures.

**43. Occipitoposterior Positions.**—The ideas intended to be conveyed by Paddock are that an early diagnosis of position and presentation should be made and that occipitoposterior positions are frequent, resulting in great fetal mortality and maternal morbidity, and should be corrected by postural measures before labor. Every case diagnosed O. D. P., should be directed to sleep on the right side and at all times when lying down to lie on that side, and to assume the knee-chest posture for ten minutes every morning. In very few cases will this method fail to bring about the desired change and labor will be correspondingly shortened.

**50. Paresis.** Norbury reports briefly three cases of paresis which seemed to take their starting point from an attack of infectious fever and concludes that while syphilis is the etiologic factor in chief the infectious fevers are contributing elements, as is also heredity.

54.—See abstract in THE JOURNAL, xxxvii, p. 995.

55.—Ibid., p. 996.

56.—Ibid.

58.—Ibid., p. 997.

**61. Intestinal Tuberculosis.**—The form here described, chronic hyperplastic tuberculosis, has been noticed of recent years and is distinctly characterized by its affecting various segments of the intestinal tube and by usually a considerable degree of thickening of the intestinal wall. Lartigau reports a case in full detail and discusses the condition generally, pointing out the gross and microscopic lesions, its point of predilection, especially near the cecum, the influence of sex, occupation, various diseases, etc., and the question whether it is primary or secondary to pulmonary disease. The case he reports, he thinks, is undoubtedly a primary case; there was no evidence of the presence of a former pulmonary tuberculosis. The symptomatology is given in general terms at the close of the article, indefinite onset, dyspepsia, vomiting, abdominal pain, possibly tympanites, later alternate diarrhea and constipation and occasionally persistent diarrhea; loss of strength and weight, evening rise of temperature, etc., are the characteristics of the earlier stages. With time the abdominal crises become accentuated and the weakness very great. Some patients suffer from recurring colic, accompanied by vomiting and constipation. The area of greatest tenderness is usually within the right iliac fossa where the symptoms of obstruction usually appear. Later the clinical picture is more and more definitely that of chronic intestinal obstruction; thus in carcinoma there may be various local abdominal distentions, some tenderness and possibly tympanites, and dullness usually present directly over the tumor. In the rectal form the hemorrhages are characteristic from the start in a large proportion of cases and stenosis develops later. As regards treatment, he thinks most cases of reported resected cancer of the regions affected are probably hyperplastic tuberculosis. The condition is a surgical one. Extirpation of diseased tissue promises good results in a large proportion of cases.

**62. Multiple Myeloma.**—The symptoms in the case reported by MacCallum were discussed by Hamburger, in the *Bulletin of the Johns Hopkins Hospital*, 1901, xxii, p. 38. They consisted of spontaneous occurrence of fractures of the bones followed by the appearance of definite soft tumor masses over various bones. No marked anemia, albumosuria. The autopsy

showed multiple new growths from the bone-marrow, not very sharply delimited from the marrow and showing very gradual transitions into it, the cells having the general form and characters of the bone-marrow cells, lacking the specific granules of the myelocytes and their formative antecedents. They differ in essential particulars from the plasma cells, and especially these facts and the fact that they largely replace the myelocytes in the neighborhood of the tumor lead the author to consider them directly related to these cells, probably derived from the large non-granular forerunners of the myelocytes. Degenerative changes, numerous cell inclusions, and the abundance of red blood cells scattered in the tumor mass have been noted. The etiology of the affection remains obscure.

**64. Strongyloides Intestinalis.**—From a discussion of the subject and a study of other cases Thayer considers himself justified in emphasizing the following points: "1. Diarrhea associated with the presence of strongyloides intestinalis occurs in the United States. 2. The observation, in the Johns Hopkins Hospital, of three cases within three years, cases originating probably in Maryland and Virginia, suggests that this parasite may be more frequent than has hitherto been supposed. 3. As in most cases originating elsewhere, in temperate climates, the development of the sexually differentiated, free living generation was in these instances apparently unusual, the direct transformation of the rhabditiform embryos into filariform larvæ predominating. 4. The discovery of the existence of strongyloides intestinalis should emphasize the possibility that Uncinaria duodenalis may also occur in this country. 5. More systematic examinations of the feces both in public clinics and in private practice are much to be desired."

**68. Tropical Diseases.**—The special forms of tropical diseases noted as prevalent in Manila by Andrews are malarial affections, enteric disorders and certain parasitic diseases. He specially mentions dengue which is generally temporary, diarrhea due to dietetic errors, malaria, dhobie itch, and ascaris lumbricoides as epidemic. The dhobie itch is simply tinea circinata, but in Manila it often causes ulcers and sometimes serious abscess and buboes. These, however, when opened and drained, give no further trouble.

**79. Oidiomycosis of the Skin.**—This article occupies the whole of the journal and is very elaborate and monographic. We can only give here a summary of the conclusions. A very extensive bibliography is appended and the paper is elaborately illustrated: "1. The so-called protozoic disease of Posadas, Wernicke, and others; Busse's and Curtis' saccharomycosis hominis; and Gilchrist's blastomycetic dermatitis are various manifestations of the same disease. 2. The condition in the skin possesses constant clinical and histological characteristics which separate it positively from all other skin diseases, particularly verrucous tuberculosis, carcinoma, and syphilis. 3. The organisms isolated from various cases, differ in minor respects among themselves, but are so closely related morphologically and biologically as to justify their inclusion in a common genus; oïdium; they are thus analogous in a pathogenetic sense to the fungi which cause actinomycosis, and to those causing trichophytosis. 4. The variations among the organisms allow the recognition of three morphologic types: a, blastomycetoid or yeast-like; b, oïdium-like; c, hyphomycetoid. 5. There are two histologic forms of the disease in the skin, the eosinophilous and the non-eosinophilous, the former being associated with the mold type of the organism. 6. In accordance with conclusion 3, oïdiomycosis is an appropriate term for the conditions caused by the organisms, and oïdiomycosis cutis for the disease as it occurs in the skin. 7. Aside from the infections considered in this communication, certain cases which have been described in the literature from time to time indicate that oïdium-like organisms may cause other severe pathologic conditions in man."

**87. Exophthalmic Goiter.**—The theories of exophthalmic goiter are noticed by Wood, who holds that it undoubtedly is due to deranged function, but just what this derangement is and its cause is not absolutely clear. The symptoms are rapidly

reviewed, and he notices particularly one which he has observed in one case, namely, fetid night sweats, which has been mentioned also by Basedow, but not noticed in many of the articles on the disease. Exophthalmus, Dalrymple's sign or retraction of the upper lid, infrequent winking, Graefe's sign, insufficiency of convergence or the sign of Möbius, Becker's sign or spontaneous pulsation of the retinal arteries, epiphora, which is still more common, dryness of the eyes, loss of sensation of the cornea and conjunctiva and various other symptoms are discussed. Of course, only a few of these may be present, and the disease may exist without at least two of its three cardinal signs and one side alone may be affected by the proptosis and other ocular symptoms. As regards treatment he is inclined to believe, from the number of medical remedies that have apparently succeeded, that a certain proportion of the cases are self-limited. He advises non-stimulating food and as much sleep as possible. As regards surgery sympathectomy has apparently done good in some cases. Thyroid excision is a serious operation which should be only performed in hopeless cases. In resorting to it one should never promise a cure and should always set forth the danger of the operation.

**82. Appendicitis in Pregnancy.**—Brothers' reports a case and quotes others from the literature of this complication and discusses its management. He thinks many cases have never been recorded because the course of the disease is too mild to excite interest and others where fatal results follow operation. The logic of conservatism in the treatment of appendicitis during the reproductive process may be summed up, he says, as follows: 1. The cardinal argument is the admitted fact that cases do recover completely without operation; 2, it is necessary to respect the popular fear of all operations, in the absence of good reasons for ignoring it; 3, "self-preservation is the first law of nature," and none of you desire another practitioner, with perhaps less conscientious scruples—and perhaps as much in need of "the root of evil" as yourself—to displace you by humoring the patient's feelings with a recommendation of delay, after you have insisted on immediate operation; 4, the still open question as to which procedure is safest for the mother, a child's life being the secondary consideration. And, finally, the knowledge that certain cases are beyond human assistance from the onset.

**85. Malignant Tumors.**—Ewing believes there is very little difference in the results obtained from surgical treatment, and he aims to notice here the special points which account for the difference of opinion in regard to the curability of cancer of the breast. In carcinoma one of the most important factors in determining the outcome is the previous duration of the disease. It is very difficult to form an estimate of the age of a carcinoma. Another less generally recognized form is that of small carcinomatous focus often existing in non-malignant tumors and these are reported as operations for malignant disease and considered as cured. If we are going to estimate the matter, the question of rapidity of growth should be considered. He recognizes among the carcinomas of the breast one group which retains more or less the adenomatous type, adeno-carcinomata which are met with under three different conditions: 1. A carcinomatous multiplication of cells in the epithelial tufts projecting into larger cystic adenomata. These should be removed early and the operation ought to be in most cases followed by permanent cure. 2. Adeno-carcinoma arising in tumors with dilated spaces in which the extensive multiple cells are confined within the original alveolus. Such tumors seldom involve the lymph nodes and their prognosis is good. 3. A type where it arises in the long quiescent gland by the increase in number and tortuosity of the secreting alveoli producing large lobules containing an excessive number of alveoli in section, while the cell multiplication often bursts the basement membrane, throwing the tumor into the class of adeno-carcinoma. The histologic structure of these indicates a moderate grade of malignancy. All these should be separated from pure carcinomas in prognosis in estimating the results of operation. The remaining group of pure carcinomata commonly described as a small or large alveolar, or encephaloid or tubular carcinoma, and the dis-

tinct sub-group of scirrhus, are another matter and he describes their characteristics. He has seldom seen a permanent cure of the tubular type in which an extension to the lymphatics measured by inches very likely occurs in a period measured by months or even weeks, although the original tumor may not appear to be growing rapidly. The alveolar on the other hand shows a greater variety of structure and greater difference in the prognosis. A lessened grade of malignancy may be expected in tumors where the alveolar tendency is permanent and where the cells divide their energies between multiplication and secretion and especially where mucoid degeneration destroys many cells which would otherwise continue to multiply. This last factor has been known to bring to a standstill this growth of glandular carcinoma and if it could be artificially introduced the malignancy might be diminished. Extreme malignancy must be ascribed, however, to glandular carcinoma in which the cells show little tendency to maintain a distinct alveolar arrangement, or even grow diffusely and the secretory function is entirely lost, the multiplication of cells not interrupted by degenerative changes, and the inflammatory process is exudative rather than productive. In both tubular and alveolar carcinomata the age of the patient and the relation of the growth to pregnancy, lactation and the menopause are of prime importance in determining prognosis. The most malignant cancers of the breast are alveolar carcinomata, first noted during or after lactation, while there is an increasing tendency toward the scirrhus type as the subjects pass the menopause. In scirrhus the grade of malignancy is always less than with the tubular variety and most of the alveolar types. Yet the lack of a prominent localized tumor secures for many of them immunity from operation until there is extensive involvement of the lymph nodes. Hence, the duration of a fibro-carcinoma is the chief factor determining the result of operation. He calls for the co-operation of surgeons and pathologists in matter to determine more accurately the relation of progress to histologic structure in these two classes of carcinoma of the breast.

87.—*Ibid.*, p. 1267.

**103. Ichthyol in Tuberculosis.**—Spangler advises the use of ichthyol in the home treatment of tuberculosis. In its method of administration he generally begins with a No. 1 empty capsule filled by the patient after each meal for the first week, adding another to the dose during the second week, and a third to each dose during the third week. This last dosage is maintained indefinitely and presents the advantage of attaining the maximum degree of tolerance in the shortest time. If eructations give special discomfort he divides the dose somewhat, giving the capsules after breakfast and at bedtime. The cough paroxysms lessen in intensity, expectoration becomes more profuse, the sputum less dense and the appetite improves. There is usually a marked weekly gain in weight. If there should be a pleuritic or pneumonic attack, ichthyol is suspended as long as the acute symptoms last and carbonate of guaiacol or other remedies substituted. Phenol hypodermically is excellent for cases associated with gastric or intestinal irritability. Strychnin in supporting doses during the early months is a valuable adjunct to treatment. He advises that all cases of obstinate cough or persistent irritation of the upper air passages, particularly that following la grippe, pneumonia or typhoid, should be placed upon ichthyol and proper habit discipline.

**111. Cholelithiasis.**—Maschke sums up our knowledge of the etiology of cholelithiasis as follows: "In cholelithiasis we have to do with a local disease, and not with any constitutional or nutritive disturbance. The presence in the bile, in insoluble form, of the two chief constituents of gallstones, cholesterin and bilirubin-calcium, is determined by local causes. The cholesterin found in gallstones has never been in solution in the bile, but is formed as a product of epithelial degeneration, and the combination of bilirubin and lime salts to form insoluble bilirubin-calcium is brought about also by the presence of albumin derived from degenerated mucus and epithe-

hial products. Thus a condition that would favor the degeneration of epithelium and the increased secretion of mucus, or in other words a catarrh, would produce these factors. As cause of the catarrh any factor that favors the stagnation of bile and thus renders infection by micro-organisms possible, is considered as the predominating influence. The bacteria involved are usually the bacillus coli, or bacillus typhosus. The general etiologic factors, age, sex, pregnancy, clothing, sedentary life; etc., only serve to bring out one important fact, that anything that favors stagnation of bile favors the occurrence of the lithogenic catarrh."

112.—See abstract in THE JOURNAL, xxxvii, p. 856.

113. **Rabies.**—Three cases are reported by Upson which have certain features of interest. In the first, which he considers a typical case, the patient was an unusually well balanced man with no hysteric tendencies, and while he diagnosed his condition himself he bore it throughout with wonderful nerve. Inoculation experiments from the cat that caused the disease produced hydrophobia in a rabbit. The second case was that of a woman who had no idea of what was the matter with her until late in the disease, but the impression produced by the aspect of the patient was not that of fear or mental depression, but such as one of an infectious disorder acting on the nerve centers and the circulation. The third case is somewhat less clearly an instance of the disease. He believes that, with the use of adequate doses of morphin, patients need suffer no more than do patients suffering with other affections hopeless from the start.

115.—See abstract in THE JOURNAL, xxxvii, p. 713.

118. **The Mosquito Investigations at New Orleans.**—Nearly the whole of this issue is taken up with the elaborate article by Beyer and Pothier, who summarize their work as follows: "We have studied the topographic and seasonal distribution of the mosquitoes infesting this city and vicinity and have determined that anopheles inhabits the swamps surrounding the city, as well as the outskirts, while stegomyia and some of the common forms of culex prevail in the heart of the city, finding their breeding-places in cisterns and gutters." They here call attention to maps of the distribution of these genera and the location of yellow fever cases in 1907. "While there is more or less striking coincidence between the distribution of stegomyia and of yellow fever cases, and while we think this is in a degree significant, we ought not to lay undue emphasis upon this fact, for reasons which will readily present themselves. The maps are as accurate as the data we have at hand, but it must be remembered that these fever cases were not checked up by blood examinations and we can not be certain that all cases reported were yellow fever, nor that all yellow fever cases were reported. Moreover, stegomyia is absent from those sections sparsely inhabited, which show no yellow fever infection, possibly because there were no inhabitants to have the disease." Experimental work with bacillus ieteroides (Sanarelli) and mosquitoes lead them to say: "1. We have established to our satisfaction that the bacillus described by Sanarelli as bacillus ieteroides is a distinct pathogenic organism. 2. We have infected stegomyia fasciata by allowing them to bite animals infected with bacillus ieteroides and suffering from a disease corresponding experimentally to yellow fever, as observed in animals (dogs and rabbits). 3. We have recovered in pure culture the bacillus ieteroides Sanarelli from these mosquitoes so infected. 4. We have produced in healthy animals the same disease by allowing some to be stung by mosquitoes infected from five to eleven days previously, and by inoculating others with cultures made from infected mosquitoes. 5. We have recovered the bacilli again from these mosquito-infected animals. 6. We have not, however, been able thus far to stain and locate the bacilli in the tissues of the mosquito when sectioned. Mosquitoes that have bitten malarial patients have been sectioned and the parasites found." Epidemiologic considerations lead the authors to believe that while anopheles maculipennis is responsible for simple tertian and quartan infection, anopheles crucians is responsible for estivo-autumnal disease.

They point out the methods of exterminating mosquitoes, abolishing surface drainage, substituting sewerage, etc., and claim credit for the following salient points established by them: "Correlation of distribution of stegomyia fasciata and of yellow fever within limits of the city. Mosquitoes may convey bacterial disease by inoculation, the organism experimented with being the one believed to be the cause of yellow fever. Confirmation of the work on malaria by English, German and Italian investigators." They believe that they "have determined that the mosquito stegomyia fasciata can inoculate the disease produced by bacillus ieteroides Sanarelli, after having had some days previously ingested blood from an animal infected with this bacillus. We have not disproven that the mosquito might convey the materies morbi simply mechanically, either by means of its mechanically infected proboscis or by means of its body, wings and legs, soiled by contact with dejecta and then touching food or drink of another individual. While this is not urged as a probable mode of infection, it is a matter that should be settled one way or the other; hence, it is a subject for future experiments. Further attempts should be made to locate the bacillus ieteroides Sanarelli within the tissues of the infected mosquito."

127. **Traumatic Aneurysm.**—Three cases are reported, with the following conclusions: "1. True traumatic aneurysms, which are unmistakably the result of traumatism inflicted on a blood vessel, modifying its integrity. 2. A limiting connective tissue wall may develop around a hematoma which is the result of an injured blood vessel and may or may not have a communication with the blood vessel. Such a condition in no sense is an aneurysm. The formation is entirely extrinsic and never was a part of the arterial wall, and therefore should not be termed an aneurysm. 3. A recent hematoma, resulting from an injury to an important blood vessel, whose limitations depend on anatomic boundaries, has even less claims than an encysted hematoma to the term aneurysm. A better term would be traumatic arterial or venous hematoma. It will be in the direction of scientific accuracy to exclude from our terminology, 'traumatic aneurysm,' all conditions which do not conform to the definition, viz., a sac formed by the dilatation of the walls of the artery, filled with blood."

138.—See abstract in THE JOURNAL, xxxvii, p. 849.

139. **Ectopoid Gestation.**—Macdonald reports a case with symptoms of bloody discharge, bearing-down pain, etc., with a large asymmetrical mass within the abdomen, which, when operated on surgically, revealed a two months' fetus under the peritoneum of the left side of the uterus which had been ruptured subperitoneally. The patient made a good recovery.

145. **Metrorrhagia.**—Hirst reports cases of metrorrhagia occurring in young girls and elderly females and offers the following as his conclusions: "There is a metrorrhagia in young girls due to glandular and interstitial endometritis, which, if neglected, may seriously impair their health; it is curable by curettement (perhaps repeated) and by the removal of any cause of pelvic congestion that may be present. There is a metrorrhagia in old women years after the menopause, not due to malignant disease (which ought always to be suspected), but to a corporeal or cervical polyp and an accompanying endometritis."

147. **Acute Peritonitis.**—The treatment suggested by Robinson is first giving no fluid or food by the mouth. Rather wash out the stomach if vomiting is active. 2. Keep the patient absolutely still on the bed, not allowing him to get up for any purpose whatever. 3. Give small doses of morphin sulphate, 1/16 gr. at intervals of two to four hours. 4. Apply continued cold to the abdomen by rubber tube-coil or rubber ice-bag; or apply continued heat by means of large cornmeal poultices. 5. To check the thirst employ rectal injections and wet gauze to the lips. 6. No ice should be allowed. Nourish with liquid foods per rectum. Give no cathartics and give the peritoneum time to produce an exudate which will imprison germs, sterilize and digest them.

148. **Methyl Alcohol Blindness.**—Burnett reviews the previous history of this form of affection and reports two

cases. He finds that so far nothing has been found that will check its results. If a poisonous amount of wood alcohol has been taken we should expect blindness more or less complete. Therefore, he suggests we should prevent the use of it and consider it one of the dangerous poisons. At present the country is flooded with a poison dangerous to vision and even life itself under various and entirely unsuspected forms in the economic use of wood alcohol.

150.—See abstract in *THE JOURNAL*, xxxvii, p. 996.

158. **Hay Fever.**—After describing the disease and its general treatment Sawyer says that his great reliance has been for some time on powdered desiccated suprarenal gland. It relieves for two or three hours and may need to be often repeated. He would carry it to the full physiologic effect of the remedy. He generally uses a from 3 to 10 per cent. solution locally by spray or on cotton, repeating when the symptoms demand it, and from 3 to 10 gr. of desiccated gland internally. He says very satisfactory results may be obtained from using it internally alone, giving it in full doses, 5 gr. every two hours until the physiologic effect is obtained and the symptoms are controlled, then diminishing in quantity until finally it is used only twice daily through the hay-fever season.

*British Medical Journal*, December 28.

**Localization in the "Motor" Cerebral Cortex.** C. S. SHERRINGTON and A. S. F. GRUENBAUM.—The authors experimented on all the known species of anthropoid apes, but mainly on the chimpanzee. They point out certain differences from current views as regards localization that have been observed in their experiments. The so-called motor area occupies unbrokenly the whole length of the precentral convolution, and in most places the greater part or the whole of its width. It also occupies the anterior wall, and in some places includes the base of the Rolandic fissure, occasionally extending even into the deeper part of the posterior wall. They have never, however, found the motor area extend to the free face of the post-central convolution. The anterior limit of the motor area is not bounded by any fissure. The front part usually dips into and across the upper part of the superior precentral fissure, and lower down it not infrequently dips into the inferior precentral fissure. Occasionally the front edge of the region dips into almost the whole length of the superior precentral sulcus. It is not the area of the motor region that is variable, but the variation is in the sulcus itself and they point out that the sulci are not strictly of value in the topography of the functional centers. There is so much individual variation that the only way of ascertaining the location is by electrodes. Two landmarks of real value are the genua of the Rolandic fissure. They were surprised by the ease with which faradization elicited movements from this so-called motor region of the cortex of the anthropoid, as their predecessors had stated that stronger currents were required than in the lower monkeys. Another point in which their results differ is that in certain individual cases the epileptiform discharges were very easily excited. They give the details of the different motor areas and remark that they have found in some cases a severe crossed brachiolegia from the excision of the hand region of the right hemisphere without the slightest sign of paresis in the face or leg. Lesions in the leg area might cause similar temporary paresis in the opposite leg. From their observations they think it probable that as much of the motor area lies hidden in the sulci as actually lies in the free surface of the convolutions, but endorse the opinion of Beever and Horsley that the so-called motor areas in anthropoid brains form only a smaller fraction of the total surfaces than is found in the lower types of the monkey.

**Theories of Inheritance.** G. ARCHDALL REID.—Reid's article is a statement of his Weismannic views as regards the non-inheritance of acquired characters. He starts with the assumption that the transmissibility of acquired characters is unbelievable, and argues therefrom. A large part of his article is an attack on Adami's views and his hypothesis of the transmission of acquired characters.

*The Lancet*, December 28.

**Early Diagnosis of Pulmonary Consumption, with Especial Reference to the Value of Tuberculin.** ARTHUR LATHAM.—The points insisted upon as important in the early diagnosis of pulmonary tuberculosis are as follows: Latham thinks we are justified in making a positive diagnosis in the vast majority of cases: 1. When we find diminished resonance and increased resistance to the finger associated with the presence of persistent crepitations or fine râles in those situations in which tuberculosis usually starts in the lungs, namely, the apices of the upper lobes, more especially towards their posterior aspect. 2. When the symptoms are suggestive of tuberculosis and tubercle bacilli are present in the sputum, though the physical signs of the lungs are absent. 3. When hemoptysis occurs in cases, to any extent whatever, where there is no evidence that bleeding comes from the upper air-passages or is dependent upon some morbid condition of the heart or other diseases within the chest. 4. When there are suspicious signs in the lungs with tuberculous disease elsewhere in the body. He illustrates these different points, calling attention particularly to careful research for trivial causes of hemoptysis. The other methods, such as agglutination of tubercle bacilli by the patient's serum, x-ray examination, etc., are not considered entirely reliable, but where the disease is so slight that the diagnosis can not be made on physical signs, or any tubercle bacilli found, he believes that one, two or three small injections of Koch's old tuberculin are absolutely free from danger. The value of this reaction is not absolute, but we may compare it with the Widal reaction in typhoid fever. He thinks that we have in it a very valuable means for making a positive diagnosis in a large number of cases which present suspicious symptoms and signs at a much earlier stage of the disease than we can by any other means.

*Journal of Tropical Medicine*, December 16.

**The New Biological Test for Blood—Its Value in Legal Medicine and in Relation to Zoologic Classification.** GEORGE H. F. NUTTALL.—The new test for blood which has been lately largely noticed, is discussed by Nuttall, who claims that we have in anti-serum a very delicate test which will have its use in legal medicine and will permit of our study of the relationship between animals. It is very remarkable that a common chemical property has persisted in the blood of anthropoids throughout the ages that have elapsed during their evolution from a common ancestor and this in spite of the food and different habits of life. Similarly the blood relationship existing between other groups of animals serves to carry us back into geological times. He believes that by means of these studies of the blood we shall have a most valuable aid in the study of the various problems of evolution. He remarks in conclusion that Uhlenhuth wrongly takes credit to himself of having discovered this test for the blood. In fact, he has discovered no new principle, but only followed the lines laid down by Tchistovitch, Bordet and Myers. While he was the first to obtain an anti-serum for the human blood and proved that reactions took place with solutions of dried blood, he is wholly unjustified in taking the credit of the method to himself, especially as he was evidently perfectly aware of the literature on the subject.

*Hospitalstidende* (Copenhagen), No. 47.

**Congenital Stenosis of the Pylorus.** HIRSCHSPRUNG.—This surgeon is inclined to favor gastrotomy with subsequent dilatation of the pylorus, which has been successfully done by Nicoll and Schmidt. It is less aggressive than gastro-enterostomy and restores natural conditions, but gastro-enterostomy has a number of successes to its credit, which he reviews in detail.

*Annales de Dermatologie (Paris), October.*

**Iodo-Mercury Cacodylate in Treatment of Syphilis.** CIVATTE and FRAISSE.—This communication from Brocq's service at the Brocq hospital describes the results of the administration of a combination of arsenic and mercury in 60 cases of syphilis. After testing various preparations a special combination was made for the purpose by dissolving 1 gm. of mercury cacodylate and 2 gm. of cacodylic acid in 75 gm. of distilled water. In another vessel 1 gm. of sodium iodid is dissolved in 5 gm. of water, and the two fluids are mixed and neutralized with dilute solution of sodium. Distilled water is then added to make 100 c.c. The resulting fluid is limpid, stable, is not decomposed by light and can be sterilized at 120 C. for twenty minutes. The dose, 1 c.c., is injected perpendicularly into the upper, outer region of the buttocks with a needle 4 cm. long. After one or two injections the dose is increased to 2 cm. No inconveniences were observed in any case. The results were so superior to mercurial treatment alone, that the addition of sodium cacodylate is evidently indicated in syphilis whenever the patient is depressed, neurasthenic or emaciated. The mixture above described is soluble and easily absorbed by the cellular tissue. It is less painful than any other mercurial preparation and simplifies treatment by administering the two drugs at once. This combined method of treatment is unnecessary for vigorous or excitable subjects, and is perhaps contra-indicated in case of consumptives with a tendency to hemoptysis.

*November.*

**Linear Dermatoses.** F. BALZER.—Two cases are described, one of nevus and the other of psoriasis, distinguished by the fact that the dermatosis occurred in stripes, horizontal, oblique or longitudinal. The nevi developed after the patient had accomplished his military service. They affected only one side of the body, and were arranged in more than sixteen stripes, four running down the leg to the middle of the calf. The psoriasis was also unilateral and most pronounced on the leg. Analysis of the cases shows that the theory of a metameric and of an embryonal origin do not exclude each other. The general cause works along the lines of least resistance, and the diminished resistance may be from some disturbance in the embryonal existence or in the innervation, either peripheral or central.

*Archives Gen. de Medecine (Paris), November.*

**Progressive Asystolia in Young Persons Due to Primary, Subacute Myocarditis.** E. JOSSEFAND.—Josseland describes three cases personally observed. The patients were young men previously healthy. They suddenly presented symptoms suggesting tuberculosis or nephritis, cough, hemoptysis, emaciation, tendency to asphyxia, edema, signs of cerebral and pulmonary embolism with a normal or nearly normal pulse and a simple bruit de galop at the heart. The affection was fatal in 4, 8 and 18 months, with no remissions.

*Gazette Heb. de Med. (Paris), November 3, No. 88.*

**Surgical Intervention for Dystocia from a Fibroma.** A. BOURSIER.—After comprehensive study of the subject Boursier concludes that total abdominal hysterectomy is the preferable operation for this condition, and should be done whether the fetus is alive or not. Symphysiotomy should be absolutely rejected, and conservative Cesarean section is indicated only in very exceptional cases. It is, however, a good operation when it can be effectually completed by myomectomy. The Porro should be reserved for certain special cases.

*No. 92.*

**Clinical Interest of Blood Ferments.** C. ACHARD.—This communication calls attention to the fact that a much lessened activity of the blood ferments—especially lipase—indicates diminished powers of resistance on the part of the economy in general, and is hence an unfavorable sign for the prognosis.

*No. 95.*

**Herpes After Spinal Cocainization.** C. ACHARD.—Violent headache and vomiting were noted in three cases, commencing soon after the injection, accompanied by higher temperature.

The herpes developed on the face after nearly forty-eight hours. Eucain was used instead of cocain in one case.

*No. 96.*

**Two Cases of Splenectomy.**—BLANQUINQUE. The spleen was removed on account of splenoregalia in one patient, who rapidly recovered. The other case was a patient with severe leukemia. The spleen weighed nearly 3.5 kilograms and was very friable, with patches of amyloid degeneration. The symptoms of leukemia had commenced in the midst of perfect health ten months before. He survived the operation only eight hours.

*Presse Medicale (Paris), December 4.*

**Lesions of the Myocardium in Uremia.** P. MERKLEN.—Three cases of subacute interstitial myocarditis of uremic origin are described. It occurred in the course of chronic nephritis complicated by acute parenchymatous nephritis. Albuminuria was abundant and rebellious in all three. One exhibited symptoms of acute edema of the lungs, another headache and coma, the third uncontrollable vomiting, metrorrhagia and hematemesia. The autopsy disclosed lesions in the myocardium similar to those observed in toxemia of an infectious origin, resembling an inflammatory edema. This uremic myocarditis caused no symptoms during life, but it throws light on various functional disturbances and chronic alterations in different organs noted in renal toxemia.

*December 7.*

**Pre-Pyloric Ulcero-Cancer.** G. HAYEM.—Eight or nine cases of cancer consecutive to a chronic ulcer have been studied by Hayem. He describes the pathologic anatomy of 5 in all their details, which seem to be largely identical in each case. The age of the patients was 40 to 53; all were men. A tumor was palpable in only one case. In 2 patients the ulcer had caused no symptoms until the cancerous degeneration occurred, when there was constantly loss of appetite, pains and vomiting of fresh or digested blood. The terminal stage was marked by asthenia, anemia and signs of dehydration. Hayem's experience indicates that this ulcero-carcinoma is the most serious of all gastric affections.

*December 14.*

**Generalized Malignant Lymphoma.** A. JOSIAS.—The child whose case is described by Josias, was 9 years old. The affection ran an almost acute course in a few months. The tonsils were first affected and a large tumor developed in one. The autopsy disclosed that the entire lymphatic system was affected, apparently a return of the lymphatic organs to the embryonal condition under the influence of some toxin. This malignant lymphadenoma seems to be an infectious disease, Josias concludes, causing a special reaction on the part of the adult lymphatic tissue or of the relics of the embryonal. Judging from the alterations in the bone marrow and in the spleen, the agent of the infection does not belong to the group of micro-organisms which have been discovered in the blood and organs in cases of pseudo-leukemia. This is proved by the absence of local polynucleosis, which differentiates the affection from the changes induced by ordinary infections.

**Typhoid Staphylococcus Infection.** E. HIRTZ.—A robust young man, addicted to drink, died in seventeen days after the commencement of an acute disease characterized by headache, epistaxis, fever, vomiting and a fetid, yellow diarrhea. The pulse was rapid and soft, the face and extremities cyanosed and death occurred in increasing dyspnea. The autopsy disclosed on nearly all the organs, but most pronounced on the kidneys, the multiple visceral emboli of experimental general staphylococcus infection. There were no cutaneous nor osteomyelitic lesions. Besides the classic cardio-renal localizations, there were also ulceration of the intestines and bulbo-medullary abscesses. The entering-point of the infection was unknown.

*Revue de Chirurgie (Paris), December.*

**Reflux in Gastro-Enterostomy.** E. TAVEL.—Tavel describes a case in which gastro-enterostomy in its various modifications was performed five times in order to relieve the symptoms of hyperchlorhydria and rebellious motor insufficiency of the stomach and post-operative reflux. The patient

was a young physician. Kocher's anterior antecolic gastro-enterostomy was first done, but was soon followed by new symptoms indicating the reflux not only of large quantities of bile but also of pancreatic juice. Mikulicz then performed a gastro-enterostomoplasty with jejuno-jejunal entero-anastomosis. The symptoms were not improved, the weight was still 10 pounds less than before the first operation. Kocher then operated on the patient, taking a fold in the afferent branch according to Hacker's method, stretching the mesentery of this afferent branch. Improvement was manifest for fifteen days, but the reflux symptoms soon recurred, although the primary symptoms of motor insufficiency had been abolished. This last operation had a favorable influence on the preceding constipation, but owing to diastasis of the recti there was hernia of the entire epigastric region. The patient clamored for a new operation and the duodenum was severed below the pylorus, under ether. The two parallel cicatrices from the previous operations were resected and the abdominal wall closed, in an operation which lasted two hours and a half. As the result of this intervention the reflux of bile was arrested but the even more disagreeable pancreatic juice still found its way into the stomach in sufficient quantities to render life a torment. The afferent branch of the anastomosis was therefore resected a few months later. The conditions, therefore, after the five operations were similar to those of the Doyen gastro-enterostomy with subpyloric section of the duodenum. The experience in this case demonstrates that the Doyen and Roux methods of gastro-enterostomy are the only ones that guarantee against reflux and of these the Roux Y is absolutely the method of choice. If dyspeptic troubles follow a palliative operation in case of cancer, the operator has no cause to reproach himself, but the case is different when the intervention was undertaken for the relief of some benign affection such as Reichmann's disease, gastro-succorhea, dilatation, ulcer, etc. The operation should never expose the patient to ills worse than his previous condition. The Y gastro-enterostomy requires possibly fifteen minutes longer, but this is nothing in comparison to the benefits attained, unless the patient is very feeble.

**Repair of Bone Marrow.** V. CORNIL.—The experimental research on dogs reported shows a remarkable power of repair after extensive destruction of the bone marrow. No septicemic phenomena were observed in any instance. In the clinical experiences that have been published, the infection of the focus in the bone has hindered or prevented repair in certain cases, but when it has been possible to control the infection, either by the natural defenses or adequate intervention, repair has occurred quite rapidly and similarly to the experimental experiences reported. Among the cases of resection on record, Sédillot describes a patient, 31 years old, operated on for suppurative coxalgia. The femur was sectioned at the lesser trochanter and the marrow cavity evacuated for 10 cm. The patient died ten months afterward from pelvic suppuration and the femur showed external or periosteal, and internal or marrow, ossification with reconstitution of the marrow cavity which was filled with a gelatiniform marrow. In all these cases the marrow was soft and fatty, probably a trophic alteration. In case of tuberculosis of the diaphyses, suppurative or fungous lesions have been cured by merely exposing the focus and curetting, preventing further infection from the focus by thermocauterizing, impregnating with zinc chlorid or pure carbolic acid or with Felizet's singeing. Protracted drainage is useful and the modifying treatment can be kept up with iodoform aided by ethyl chlorid. In case of acute osteomyelitis it is possible to drain the marrow cavity by passing a drain throughout the entire cavity of the diaphysis of the tibia for instance, using a long, flexible probe to introduce it through a trephining opening. There is no hemorrhage from this procedure as the writer has established on dogs, and Verj and Tscherning in the clinic. In case of neuralgic osteitis, trephining has a tendency to abolish the pain, Gosselin has found, by destroying the nerve filaments or by inducing an acute attack of osteitis which terminates in resolution. Ollier operated on a case of this kind in a syphilitic. The wound was

left open a long time and the pains were definitely abolished. Numerous cases of these various bone affections and their operative treatment are described in detail.

**Tumors of the Tubes.** E. QUENU.—Eighteen pages are devoted to the tabulated observations of tumors of the tubes by various writers, and Quenu describes three personal cases. This and the preceding article are concluded from the October number.

**Tuberculous Rheumatism.** M. PATEL.—Articular manifestations in the course of tuberculosis have been, until recently, attributed to rheumatic complications. The pathologic anatomy of the joint and positive inoculations have confirmed the tuberculous, toxic character of these joint lesions which may range from simple arthralgia to the classic white swelling, acute or chronic articular rheumatism, even the nodular and deforming varieties, attenuated or not according to the virulence, their number, the general condition of the subject or the local condition of the point affected. Patel describes a number of typical cases of each variety.

*Revue de Gynecologie (Paris), v. 4 and 5.*

**Relations Between Deciduomata and Moles.** E. BONNAIRE.—Metoiz has recently reported that in 48 out of 98 cases of deciduoma which he had collected, a vesicular mole had previously been observed. An abortion or hydatiform degeneration of the chorionic villi usually precedes the development of a deciduoma. Every woman who has had a hydatid mole should be regarded, Bonnaire insists, as menaced with malignant deciduoma during the following two or three years, at least, unless a normal pregnancy intervenes. The vesicular mass should be removed with the fingers or a blunt curette. The fingers or instrument should not be allowed to press against the wall of the uterus, as it is liable to be thin and friable. The removal of the mole should be followed by a dilating antiseptic and hemostatic tamponing to induce the muscle to contract and recuperate consistency and thickness. The cavity left by the mole should be swabbed with creosote or zinc chlorid. The uterus should be curetted again the tenth to fifteenth day. If an atypical metrorrhagia persists or recurs after these procedures the inoculation of the uterus muscle with cancerous elements should be considered probable and the organ should be removed, even if it is impossible to detect any intra-uterine nodule or ulceration by digital palpation or by microscopic examination of the scrapings. Hydatid mole frequently follows an old endometritis. Menu found only 12 cases in 79 in which a hydatid mole had occurred without a preceding childbirth. The patients are usually 25 to 30 years old. Loehlein observed one case in which the neoplasm developed after the second year, but in a personal case described by Bonnaire the mole was removed three weeks after the first symptom, a profuse hemorrhage, had been noted. The hemorrhages soon recurred and vaginal hysterectomy was done a month later. The patient succumbed in forty-eight hours to the excessive anemia. The ovaries were in cystic degeneration; this coincidence has been frequently noted. The microscope showed the exclusive participation of the plasmodium in the evolution of the placentoma.

**Vaginal Enucleation of Myomata.** L. DARTIGUES.—This article describes and illustrates the technique of Segond's method of enucleating submucous sessile or interstitial myomata, with or without morcellement, by uni- or bi-lateral cervico-vaginal hysterotomy. The morcellement is done with a corkscrew inserted in the tumor. This portion is then excised by passing a curved knife around it. By this means cone-shaped pieces are removed until all is gone. The requisites are an approximately regular shape, a movable tumor and the probability that it is single and that the adnexa are sound. This operation may also be indicated under other conditions as a temporary measure. The harmlessness and the conservative character of the intervention commend it for young women and also during the period around the menopause, on account of the importance of the uterus from the point of view of the pelvic statics. About 1200 gm. is the

largest size that can be successfully ablated by this method. The results have been exceptionally brilliant in Segond's experience in many patients whose general condition prohibited a major operation. In all his numerous cases the undeniable advantages of the operation have demonstrated that it is entitled to a prominent place among conservative operations. The exact conditions in 25 cases are illustrated. Only one patient died.

Semaine Medicale (Paris), December 18.

**Comparative Measurements of the Heart.** POTAIN.—This is the last work from the pen of the late Prof. Potain and is published with an extended notice of his career and a reproduction of the plaque which was to have been presented to him on his anniversary. He compares radiography and percussion and states that the former has given us confidence in the findings of the latter, impossible to be attained in any other way. But at the same time he warns young practitioners not to be satisfied with radiography alone.

Centralblatt der Bakteriologie (Jena), xxx, 17.

**Bacteria in School Dust.** E. CACACE.—A bacteriologic study was made of dust from the various rooms of the normal school at Padua, taken at different times throughout an entire year. All the guinea-pigs and rabbits inoculated with the dust died with indications of septicemia, and the colon bacillus and the staphylococcus aureus and albus could be cultivated from the blood of heart and spleen. A remarkable fact noticed was the complete absence of tubercle bacilli. None were found at any time. Another fact was the great increase in numbers and virulence of the bacilli during the month of June. The pneumococcus was found once. The largest number of germs was found in the dust from the kindergarten room. None of the animals exhibited any symptoms of tetanus. The colon bacillus was numerous and always virulent.

No. 18.

**New Facts Learned from Agglutination Tests with Vibriones.** J. H. F. KOHLBRUGGE.—The relative virulence of a bacterium and the proportion of toxins in a sterilized bouillon can both be ascertained from the agglutination of the bacterium by the toxin, Kohlbrugge announces. The phenomenon is most conveniently observed in a hanging drop. Vibriones are rapidly agglutinated by the toxins from a more virulent vibrio. The toxins, he thinks, are secreted by the microorganisms.

No. 19.

**Visible Evidence of Action of Alexins.** A. PETTERSSON.—Interesting tests of the bactericidal and hemolytic properties of blood serum, that is, of the alexins which it contains, can be made in a test tube. The tube is partly filled with nutrient gelatin and sown with the typhoid or other bacillus. A layer of serum is then poured on top of the gelatin. Albuminous substances diffuse through the upper portion of the gelatin and this occurs also in the case of serum. Its elements permeate the gelatin to a certain depth. The bacilli proliferate below but never grow upward into the layer of gelatin in contact with the serum. It remains clear and comparatively transparent. The hemolytic action of an "active" serum can be demonstrated in this way even more distinctly.

No. 20.

**Intracellular Constituents of the Typhoid Bacillus.** A. MACFADYEN AND S. ROWLAND.—This communication reports the results of a study of the question of immunity from a new standpoint, the intracellular factors of health and disease, both as regards the micro-organism and the soil on which it grows. This has been accomplished by obtaining the cell substance from the living cell free from all secreted or excreted substances. Cell plasma from the typhoid bacillus was chosen for the experiments and the result demonstrated the astonishing fact that a single injection of 1, .5 or even .2 c.c. of the cell plasma, either subcutaneous or into the peritoneal cavity, completely protected guinea-pigs and rabbits against a certain lethal dose of typhoid bacilli. The protection afforded was complete even when tested against six lethal doses. The

animals are all alive and well six months later. The protection from a single injection did not last longer than about four weeks. The tolerance displayed by the guinea-pigs to large doses of the typhoid cell plasma was most remarkable. The plasma was rapidly absorbed with no local irritation, even in subcutaneous injections. The cell plasma after the addition of thymol was kept in a cold place for four months without losing its immunizing properties. In addition to the protection afforded by the injections the blood of the treated animals showed marked agglutinating power in the Widal test for three months afterward in guinea-pigs and for nine months in rabbits. The protection and the agglutinating property did not parallel each other. The bacilli were at first disintegrated with sand, but the technique as now improved dispenses with the sand. The trituration is at present accomplished by increasing the brittleness of the cells by freezing them at the temperature of liquid air. [The article is in English.]

Beitraege z. path. Anat. (Jena), xxx, 3.

**Angiosclerosis in the Pulmonary Circulation.** H. BRUENING.—Out of 21 cases of angiosclerosis of the pulmonary circulation observed by Bruening, the lesions were macroscopic in 9. In 7 there was no concomitant sclerosis of the aorta. The sclerosis was most marked in the arteries and veins of the lungs, occasionally in the bronchial arteries, never in bronchial veins. In one instance the sclerosis was very pronounced in the lung vessels while the rest of the body was exempt. In 6 patients there was mitral insufficiency; in 4 degeneration of the heart muscle, especially of the left ventricle and in 11 pathologic conditions in the respiratory organs which rendered respiration difficult.

**Osteogenesis Imperfecta.** F. HARNITZ.—A case of the so-called "fetal rachitis" is illustrated. The head and trunk were normally developed but the long bones were abnormally short and small, with numerous fractures. The bones showed the same microscopic characteristics as in cretinism, but the glands were apparently normal except for the fact that no iodine could be detected in the thyroid gland. The microscopic findings were diametrically the reverse of those noted in rachitic and syphilitic osteochondritis.

Centralblatt f. Gyn. (Leipzig), November 23.

**Premature Detachment of Normally Located Placenta.** W. RUEHL.—According to Goodell's statistics, only 6 children and 52 of the mothers were saved in 106 cases of this dangerous complication of pregnancy. Ruehl believes that the fetus succumbs to the interruption of the circulation, the mother to hemorrhage from the uterine wall. He describes a personal case, the patient a healthy ii-para. The previous day she had experienced a slight contusion of the abdomen. A few pains suggesting labor were followed by a sudden intense pain with a sensation as if something had torn loose inside, moderate vaginal hemorrhage, and loss of consciousness for a time, followed by violent labor pains, the hemorrhage increasing while they lasted. Attempts to dilate the cervix with the colpeurynter were abandoned as the patient collapsed, with indications of rapidly increasing distension of the uterus from internal hemorrhage. Vaginal Cesarean section was done and the fetus extracted, all in six minutes. The hemorrhage ceased as soon as the uterus was cleared. The patient recovered after hovering for twenty hours between life and death. She evidently owed her life to the rapidity with which the vaginal Cesarean section can be done.

**Treatment of Eclampsia.** W. STROGANOFF.—This method of treating eclampsia has been fully described in THE JOURNAL. Stroganoff now has an experience of 113 cases of puerperal eclampsia, which he considers an acute infectious disease. Three patients died from a complicating pneumonia, one from a septic process twenty-seven days after cessation of the eclampsia and two were moribund when first seen—a total of 6 deaths in the 113 cases.

November 30.

**Treatment of Dysmenorrhea.** A. THEILHABER.—According to Theilhaber's theory, many cases of dysmenorrhea are

due to a tetanic contraction of the sphincter of the internal os. Such contractions of unstriated muscle are always painful, as in cramps of the pylorus, anus, etc. They can be prevented by excision of a small wedge-shaped piece out of the sphincter. He uses a small knife for the purpose of curing dysmenorrhoea on this principle, made in such a way that it can not penetrate more than 6 cm. into the tissues. His results have been extremely satisfactory in twenty-two cases in which he has applied this measure after the failure of general and local treatment.

December 7.

**Survival After Extirpation of Carcinoma.** E. WALDSTEIN.—The experiences at Schauta's clinic demonstrate that 4 out of every 100 women with cancer can be permanently cured. Only 14.7 of the entire number of cases of cancer that came to the clinic were in an operable stage. The operation was by the vaginal route in 112 followed to date, and 28 are permanently cured. Schauta's statistics show 26.4 per cent. of the cases of the collum, without recurrence to date, and 83 per cent. of 6 cases of cancer of the corpus without recurrence.

Centralblatt f. Chirurgie (Leipsic), December 21.

**New Treatment of Exstrophy of the Bladder.** W. SUBBOTIN.—This Russian surgeon has operated with brilliant success on two patients with exstrophy of the bladder, epispadias and incontinence of urine, by constructing a new bladder and urethra, with a sphincter, out of the rectum. He incises and opens the rectum from the rear after resection of the coccyx.

He then incises the anterior wall of the rectum for 3 cm. and also incises the posterior wall of the bladder as it is pushed into the opening in the rectum by the finger of an assistant introduced from the front. This anastomosis between bladder and rectum is then carefully sutured. A flap is then cut in the anterior wall of the rectum, shaped like a long horseshoe, the very narrow base consisting of a portion of the anus. The flap includes about one-third of the circumference of the rectum. The edges are loosened, brought up and sutured together, thus forming a pear-shaped cavity inside the rectum, with a broad communication into the bladder and the natural sphincter of the portion of the anus below. This new cavity is entirely separate from the cavity of the rectum proper. It performs the functions of bladder and urethra with perfect success. The urine is spontaneously voided after due warning five or six times a day and there is no interference with the normal functions of the rectum. The patients have been permanently freed from their incontinence and the conditions have remained as satisfactory as at first after ten months in the first and six in the second case.

Deutsche Med. Wochenschrift (Leipsic), December 12.

**Extermination of Rats.** R. ABEL.—Cultures of the Danyasz bacillus in Abel's tests were found effective in some cases and not in others. In one large stable infested with rats, after the death of one rat and one mouse, the rest vanished completely and permanently. The mouse typhoid bacillus has proved almost invariably successful in his experience, and the occasional success with the Danyasz bacillus should encourage further trials. It might be possible to utilize also Issatschenko's bacillus for the purpose. It belongs to the coli group and has proved pathogenic for rats.

**Pseudo-Fibrinous Formation in Urine.** A. ROTHSCHILD.—Seven cases have been published in which a semi-solid, fibrin-like worm has been spontaneously voided in the urine. It was ascribed to a membranous ureteritis by some, by others to a pyelitis, etc. Rothschild describes a recent case in which a worm-shaped coagulum of this kind was passed in the urine. It did not take the Weigert fibrin stain, and the microscope showed that it was a structureless mass. Four months later the patient returned much emaciated with pains and a tumor in the left kidney. The nephrectomy disclosed a sarcoma with giant cells at the upper pole of the kidney. A brownish concrement was found in an ampulla in the ureter near the pelvis, and behind this concrement was a mass of substance identical with that of the fibrin-like worm voided. The discovery of such a structureless formation in the urine, especially when blood can be determined in the urine with or without the microscope, should suggest the possibility of a tumor. Fürbringer and Alexander have observed a somewhat similar phenomenon in three cases of typhoid fever. In Rothschild's case the patient was apparently healthy, with merely a history of hematuria for three weeks in 1897, for three days in 1900, and a few months later, the expulsion of the coagulum after three days of discomfort in the bladder region.

Muenchener Med. Wochenschrift, December 10.

**Medicinal Treatment of Fever in Tuberculosis.** F. KOEHLER.—It is a great mistake, Koehler thinks, to rely too exclusively on dietetic and physical measures in the treatment of tuberculosis, and omit to control the symptoms and especially the fever, with appropriate medication. All the other symptoms improve after the fever is brought under control.

**Temperature in Consumptives After Exertion.** A. OTT.—Twenty-five tuberculous subjects with normal temperature showed the usual slight rise in temperature after a walk, and examination of the urine demonstrated the presence of albumoses as positive in 9 and probable in 10 more. The finding of albumoses in the urine is generally accepted as an indication of fever, and consequently even this slight temperature after exertion must be regarded as fever induced by the exercise. The fact also that overexertion by a consumptive has frequently been the starting point of a protracted fever, confirms the connection between exercise and the higher temperature, and indicates the necessity of restricting the exercise to the amount below that followed by fever.

**Gelatin in Hemoptysis.** A. HAMMELBACHER.—Subcutaneous injections of gelatin were applied in four cases of rebellious and recurring tuberculous hemorrhages from the lungs. In each patient the hemorrhages became less frequent and less in amount until they ceased completely. The injections were made in the breast or thigh, from 20 to 120 c.c. at a time of a 2.5 per cent. neutralized solution of gelatin in physiologic salt solution. The injections were not painful at first but after two or three hours were painful for a time. The pain was usually controlled by warm compresses. A peculiar taste like sealing wax or mucilage was noticed in the mouth for a day or so after each injection.

**Hemoglobinometer.** GAERTNER.—This new apparatus for the determination of the proportion of hemoglobin in the blood is called the "hemophotograph," as it is used with sensitized or photograph printing papers. Light passes through a thin layer of pure water and acts on photograph printing paper

below as if nothing intervened. But blood is comparatively impermeable for the light. Diluted blood will also arrest the light according to the proportion of blood in the fluid. The apparatus is constructed on this principle. A strip of glass is made clear at one end, gradually becoming darker, that is, non-transparent, toward the other end. One side of the strip is marked with a graduated scale in millimeters. It fits into a frame like an ordinary photographic printing frame, extending through the center from end to end. On one side of it is a square frame with a large hole in the center, which is the "chamber" to hold the blood. Glass above and below protects it. After the sensitized paper is inserted in the frame, it is exposed to gas, lamp or incandescent electric light for a few minutes, until the paper under the solution of blood has turned the proper shade, determined by comparison with a strip of the color painted on the glass. The photograph thus obtained is then compared with the paper under the strip with the scale, and the figure of the scale corresponding to the exact shade is recorded. This apparatus is surprisingly exact and shows even very slight variations in the proportion of hemoglobin, impossible to detect by other means. The photographs thus obtained are valuable for reference later and the technique is so simple that it is mastered at the first attempt.

**Guide for Stomach Tube.** W. N. CLEMM.—The principal advantage claimed by Clemm for this contrivance is that it clears the fenestra in the sound. The flexible wire terminates below in a metal "basket" like an inverted cap with ear pads. The projecting portions serve as knives to cut any fragments of meat, etc., which may become lodged in the fenestra.

December 17.

**Cutaneous Symptom Accompanying Malignant Disease.** LESER. Leser has noticed that his patients with cancer exhibited numbers of small angiomas—bluish-red tumors in the skin. He has noticed this coincidence in all his 60 cases, and Mueller in 49 out of 50. Nothing of the kind was found in 300 patients with other surgical or internal affections. The average number was more than 15; 58 were noticed in one case of mammary cancer and 216 on another patient. The majority of the angiomas in the last case developed within two months. Such tumors are rare under 50 years of age, and their appearance in large numbers in a comparatively young person may be accepted as an aid in the diagnosis of a malignant neoplasm. Freund and Hollaender, he adds, have also recently called attention to the presence of such angiomas as suspicious of cancer.

Therapie der Gegenwart (Berlin), December.

**Indications and Contra Indications for Lavage of the Stomach.** L. BOAS.—Lavage of the stomach is not considered such an innocent measure by Boas as is generally accepted. It causes now and then a little bleeding, and this may be followed sooner or later by an erosion or even ulceration. THE JOURNAL has mentioned Bendersky's recommendation of lavage of the stomach as a means of treating nervous vomiting. Boas states that he has never found it necessary in any of his cases of this kind, as the patients have always recovered with repose, iced milk and occasionally small doses of some bromid. He is inclined to restrict the washing of the stomach to cases of marked dilatation or possibly certain cases of intestinal occlusion. He believes that it is absolutely contra indicated in chronic gastritis without a specially excessive secretion of mucus; also in case of ulcer unless complicated by severe motor disturbances. Ewald and Minkowski have recommended rinsing the stomach with iced water as a last resort in profuse hemorrhage from the stomach. Lavage of the stomach has been frequently applied in functional affections, with considerable success, but Boas is convinced that the same results could have been attained with simpler measures, such as self-lavage as he calls the drinking of Carlsbad and other mineral waters. Lavage is useful with moderate retention in case of stenosis of the pylorus or carcinoma of the stomach, but not to the extent that some advise. A thorough washing once or twice a week is usually sufficient. The conditions are very different in case

of carcinoma of the pylorus, especially if accompanied by much "coffee dregs" in the stomach. Such patients are liable to collapse after repeated lavage of the stomach. One of his patients grew worse so rapidly after the lavages that they were abandoned and he recuperated after their discontinuance. It is possible that the sound may cause renewed hemorrhage in these cases, or the sudden transition of the stomach from a distended to a contracted condition may entail a kind of shock. Severe ulcerating carcinoma is therefore a contra-indication to washing the stomach. The stagnation can be partially remedied by inserting the sound once or several times a day and removing part of the stagnating debris. This measure requires only a few minutes, and relieves to a certain extent the disturbances resulting from over-distension of the stomach. He asserts that there is no rational basis for lavage in case of atony with or without gastroparesis. Regulation of the diet will achieve the desired result, supplemented by alkalies, and possibly, small doses of morphin, codein or belladonna to dispel the pain at the height of digestion.

**Phosphorus in Rachitis.** H. LEO.—No conclusive proof has yet been offered of a specific action of phosphorus in rachitis, Leo remarks. On the other hand, he says, cases have been published showing an actually deleterious influence. THE JOURNAL has mentioned Nebelthaus's experience, the death of a well-developed child of two years after taking only 3 mg. of phosphorus in the course of sixty hours. Leo relies principally on dietetic and hygienic measures, especially the systematic administration of olive oil. If no improvement follows this treatment, he gives phosphorus in small doses, not over one teaspoonful of a .001 per cent. solution or ten drops of a .01 per cent.

Wiener Klinische Rundschau, December 8.

**Experiences with Spinal Anesthesia.** W. KOPFSTEIN.—Alpha eucain was used in 4 operations and tropacocain in 40. Kopfstein injected 3 cc. of the eucain and reports that severe collapse, high temperature and intolerable headache were observed in 3 cases, and in all a remarkable painfulness at the site of the operation commencing a few hours afterward. The fourth patient was a man of 27 operated on for an anal fistula. The only symptom observed was a temperature of 40 C. for twenty-four hours, but when seen again four months later, the knee-jerk was found exaggerated. The patient also complained of formication and frequent sacral pains and stated that his legs had been weak since the operation. The experiences with tropacocain were more favorable. It never induced fever. The dose injected was from 4 to 5 cc., and in 27 cases the results were very fine. Several of the patients were elderly and arteriosclerotic, but the Bassini operation, herniotomy or extirpation of the rectum were performed smoothly and perfectly without leaving traces of the anesthesia, which certainly would not have occurred with chloroform. An injection of 5 cc. of tropacocain in 3 men, 77 to 78 years old, induced complete anesthesia during amputation of the leg or thigh on account of senile gangrene. The general condition was so miserable that they probably would not have survived a chloroform anesthesia. None of these 27 cases exhibited the slightest symptom attributable to the anesthesia. In 5 other cases the anesthesia was perfect, but a violent reaction occurred afterward, with severe collapse in one. The patients were between 17 and 46 years. The collapse occurred one hour after circular extirpation of hemorrhoids. The pulse was only 48. The heart action improved the next day, but the general depression with pallor and loss of appetite lasted for three weeks. In 8 other cases no anesthesia followed the injection, but the patients reacted with vomiting, headache and intense pain in the spine. The operation was postponed in all but 2. He observed that the reaction was less violent after a good breakfast and the heart stimulated with coffee or wine, and his experiences have been more favorable since he noticed this fact and acted upon it. The possibility that the anesthesia may fail, as occurred in 20 per cent. of his cases as above described, should impose caution in adopting this method of analgesia in urgent cases.

Gazzetta degli Ospedali (Milan), December 1.

**Experimental Vaccination with Fraenkel's Bacillus.** G. TIZZONI.—The animals that bore with little disturbance a small dose of a virulent culture of the bacillus, proved more resistant afterwards when a larger dose was injected of the same or even more virulent culture, in Tizzoni's experiments. These facts suggested the possibility of successful serotherapeutic vaccination and further experiences have confirmed its feasibility. Sixteen animals were vaccinated in a vein or under the skin or in the trachea or by all three routes. A single injection was sufficient in some instances and as many as fourteen were made in others. Animals thus injected with a single loop of the culture were able to tolerate a fatal dose, eleven days later, while the control animals all died. If 5 c.c. of the filtrate were injected into a vein, the fatal dose could be safely administered in two days, but certain symptoms indicated that the immunity was not quite complete. The tests showed that the different culture media and conditions of the culture have the same influence on its vaccinating power as they display in regard to its virulence and toxic properties. Intravenous injections evidently induced a more complete immunity than by any other route. The vaccination also proved more effective and more readily obtained, the less the disturbance caused by the injections. The best immunizing results were obtained ten to fifteen days after the vaccinating injections. The immunity is more complete against the fever and marasmus than against the disturbances in the nervous system.

**Treatment of Chorea.**—Jemma reports the successful application of lumbar puncture in two cases of distressing chorea in children.

Hygiea (Stockholm), September.

**Larva in Eye.** K. STALBERG.—A larva, 1 cm. in length, was removed from the anterior chamber of the eye of a 5-year-old girl. It had probably been in the eye for five months, as the inflammation had lasted this length of time.

Revista Med. del Uruguay (Montevideo), November 1.

**Tea-Kettle Laryngitis.** L. MORQUIO.—Five cases of severe edematous laryngitis in children 2 or 3 years of age, caused by sucking the spout of a tea-kettle full of boiling water, have recently come under Morquio's care. Twenty-four hours usually decide the child's fate as the condition rapidly alters for better or worse. Three required tracheotomy on account of the suffocation induced by the excessive edema and secretions. One died in two days. The second had apparently recovered from the burn and consecutive bronchopneumonia, when a fulminating hemorrhage occurred fourteen days after the scalding. No autopsy was allowed. The other children recovered. Treatment was local with a solution of boric acid, application of picric acid, and calomel internally. Cold compresses were applied to the neck.

## Queries and Minor Notes.

### IS ABORTION JUSTIFIABLE IN THE INSANE PREGNANT?

MARION, IND., Jan. 7, 1902.

*To the Editor:*—In THE JOURNAL of Jan. 4, 1902, I find the following query: "A young woman shortly after marriage was discovered to be mentally unsound, the character of her condition being akin to paranoia. Her husband is a neurasthenic with a bad heredity. Her mother is a paranoiac and has been in an asylum for thirty-five years. Her father was an inebriate. This woman is pregnant. Whether pregnancy will affect her mental condition favorably or unfavorably is uncertain; probably it will affect it very little either way. But there is little doubt that the child would be a degenerate. Now, would it be justifiable to produce an abortion to prevent the birth of such a child, or could such a procedure under the circumstances be a crime?" Your reply to the above is: "It would be criminal."

There are tens of thousands of intelligent people in and outside of the medical profession who join with me in asking you why it would be a crime.

D. E. M.

*Ans.*—It is criminal, because the laws in regard to criminal abortion make no exceptions for such conditions. We do not care to discuss the propriety of modification of the law.

### CARD ANNOUNCEMENTS IN COUNTRY PAPERS.

WHITE BIRD, IDAHO, Dec. 31, 1901.

*To the Editor:*—Is the matter of announcing the name and occupation in a local paper professional or is it considered advertising? (See example in enclosed clippings.) Most regular physicians in this county have their name and profession in the paper.

W. A. F.

*Ans.*—The clippings enclosed contain simply card announcements of physicians that appear in country papers, giving the name, office and residence address. These are perfectly ethical and proper, according to the spirit of the Code. One physician gives the practice as limited to diseases of the eye, ear, nose and throat, which is also correct, provided it is a statement of absolute fact. In small towns this practice of inserting a card is common.

### PRAIRIE ITCH.

RANSOM, KAN., Jan. 11, 1902.

*To the Editor:*—Can you give a satisfactory treatment for the affection vulgarly known as "prairie itch," "Kansas itch," and "prairie digs?" I have been unable to find the affection satisfactorily described in the text-books, but it seems to me to be a sub-acute variety of urticaria.

W. S. G.

*Ans.*—"Prairie itch," like many other common terms, has no very definite signification; it may mean one thing in one locality and something else in another. It is a name, as a prominent dermatologist once put it, based on a want of knowledge of skin diseases. Most cases are probably some form of eczema; some are true scabies, and it is sometimes applied to various pruritic and urticarial conditions. The subject was discussed by Dr. W. T. Comlet in THE JOURNAL for October 13, 1888.

### New Patents.

Patents of interest to physicians, December 17 and 24:

- 688,935. Apparatus for examining cavities in the human body. Sylvanus B. Crane, Perry, Iowa.
- 688,936. Artificial limb. David Devol, Grandbay, Ala.
- 688,987. Optical instrument for measuring the distance between the eyes. Emil Donitz, Jena, Germany.
- 689,355. Atomizer. Anton C. Eggers, Brooklyn, N. Y.
- 688,859. Disinfecting cloth and making same. Alfred Just, Mannheim, Germany.
- 688,864. Inhaler. Solomon M. Kemp, Baltimore, Md.
- 689,107. Disinfecting apparatus. Welam L. Mitchell, Brooklyn, N. Y.
- 688,881. Syringe-nozzle. Russell Parker, Brooklyn, N. Y.
- 689,023. Precipitating casein. Maximilian Riegel, Berlin, Germany.
- 689,718. Suspensory. Wm. J. Hay, Oshkosh, Wis.
- 689,818. Syringe. Addison W. Hitt, San Francisco, Cal.
- 689,808. Surgeon's sponge substitute. Robert W. Johnson, New Brunswick, N. J.
- 689,406. Electric exercising apparatus. Alfred Olson, San Diego, Cal.
- 689,652. Exercising device. Edmund Perry, Cardiff, England.
- 689,831. Fracture apparatus. John W. Pettie, Denver, Colo.
- 689,752. Suspensory bandage. Lee Rogers and J. E. Cuthbert, Petersburg, Va.
- 689,418. Exercising apparatus. Michael B. Ryan, Cologne, Germany.
- 689,602. Sanitary garment. George Turner, Schuyler Lake, N. Y.
- 35,468. Design, druggists' label case. A. S. Baird, New York City.
- 35,469. Design, retinoscope member. T. H. Bickerton, Liverpool, England.

## Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE 32D ANNUAL REPORT OF THE STATE BOARD OF HEALTH OF MASSACHUSETTS. Cloth. Pp. 891. Boston: Wright & Potter, 1901.

LE MALATTIE DEL SANGUE. Manuale di Ematologia. Dottor Emilio Rebuschini. Un vol. di pag. viii-432. Milano: Urico Hoeppli, 1902.

THE 35TH ANNUAL REPORT OF THE CENTRAL FREE DISPENSARY OF WEST CHICAGO, for the Year Ending Nov. 30, 1901. Paper. Pp. 24. Chicago: A. L. Swift & Co., 1901.

TRANSACTIONS OF THE NEW HAMPSHIRE MEDICAL SOCIETY, at the 110th Anniversary, held at Concord, May 16 and 17, 1901. Cloth. Pp. 347. Concord, N. H.: Ira C. Evans, 1901.

TRANSACTIONS OF THE COLORADO STATE MEDICAL SOCIETY. Thirty-first Annual Convention. By-laws and List of Members. Cloth. Pp. 548. Denver: Published by the Society, 1901.

ANNUAL REPORT OF THE CHIEF SURGEON, Division of the Philippines, for the Period Ending May 16, 1901. By Col. Charles R. Greenleaf, Assistant Surgeon-General, U. S. A. Paper. Pp. 24.

TRANSACTIONS OF THE 31ST ANNUAL SESSION OF THE MEDICAL SOCIETY OF VIRGINIA, Held in Charlottesville, Oct. 23-25, 1900. Cloth. Pp. 380, xevii. Richmond, Va.: Williams Printing Co., 1901.

KIRKE'S HANDBOOK OF PHYSIOLOGY. By W. D. Halliburton, M.D., F.R.S., Professor of Physiology, King's College, London. Seventeenth Edition, with 681 illustrations. 12mo, 888 pages. Price, \$3.00 net. Philadelphia: P. Blakiston's Son & Co., 1901.

**BRIEF MANUAL OF PRESCRIPTION WRITING** in Latin or English for the Use of Physicians, Pharmacists, and Medical and Pharmaceutical Students. By M. L. Neff, A.M., M.D., Cedar Rapids, Iowa. Pp. v+152. Size, 8x5½ inches. Extra Cloth, 75 cents net. Philadelphia: P. A. Davis Co. 1901.

**STUDIES IN THE PSYCHOLOGY OF SEX. SEXUAL INVERSION.** By Havelock Ellis, L.S.A. (England), Fellow of the Medical Society of New York and the Anthropological Society of Berlin. Pp. xi+272. Size, 8½x5½ inches. Extra Cloth, \$2.00 net. Philadelphia: P. A. Davis Co. 1901.

**OUTLINES OF GYNECOLOGICAL PATHOLOGY AND MORBID ANATOMY.** By C. Hubert Roberts, M.D., Lond., F.R.C.S. Eng., M.R.C.P., Physician to the Samaritan Free Hospital for Women. With 151 Illustrations, Mostly Original. Pp. 339. Price, \$6.00 net. Philadelphia: P. Blakiston's Son & Co. 1901.

**A LABORATORY GUIDE TO THE STUDY OF QUALITATIVE ANALYSIS.** By E. H. S. Bailey, Ph.D., Professor of Chemistry, and Hamilton P. Cady, A.B., Assistant Professor of Chemistry, in the University of Kansas. Fourth Edition. 12mo, 235 pages. Price, \$1.25 net. Philadelphia: P. Blakiston's Son & Co. 1901.

**THE FOUR EPOCHS OF WOMAN'S LIFE. A Study in Hygiene.** By Anna M. Galbraith, M.D., Author of "Hygiene and Physical Culture for Women." With an Introductory Note by John H. Mosser, M.D., Professor of Clinical Medicine, University of Pennsylvania. 12mo volume of 200 pages. Cloth, \$1.25 net. Philadelphia and London: W. B. Saunders & Co. 1901.

**MANUAL OF PHYSICAL DIAGNOSIS.** For the Use of Students and Physicians. By James Tyson, M.D., Professor of Medicine in the University of Pennsylvania and Physician to the University Hospital. Fourth Edition, Revised and Enlarged, with Colored and other Illustrations. 12mo. Cloth, \$1.50 net. Philadelphia: P. Blakiston's Son & Co. 1901.

**VENEREAL DISEASES. A Manual for Students and Practitioners.** By James R. Hayden, M.D., Chief of Clinic and Instructor in Venereal and Genito-Urinary Diseases at the College of Physicians and Surgeons, New York. Third and Revised Edition. Illustrated with 66 Engravings. Cloth. Pp. 301. Price, \$1.75. Philadelphia and New York: Lea Brothers & Co. 1901.

**PHOTOGRAPHIC ATLAS OF THE DISEASES OF THE SKIN. A Series of 80 Plates, Comprising More Than 100 Illustrations, with Descriptive Text, and a Treatise on Cutaneous Therapeutics.** By George Henry Fox, A.M., M.D., Clinical Professor of Diseases of the Skin, College of Physicians and Surgeons, N. Y. Part VII. Philadelphia and London: J. B. Lippincott Co. 1901.

**ESSENTIALS OF PHYSIOLOGY.** Prepared Especially for Students of Medicine, and Arranged with Questions Following Each Chapter. By Sidney P. Budgett, M.D., Professor of Physiology, Medical Department of Washington University St. Louis. 16mo volume of 233 pages, finely illustrated with many full-page half-tones. Cloth, \$1.00 net. Philadelphia and London: W. B. Saunders & Co. 1901.

**A MANUAL OF MINOR SURGERY AND BANDAGING.** For the Use of House Surgeons, Dressers and Junior Practitioners. By Christopher Heath, F.R.C.S., L.D.S., Consulting Surgeon to University College Hospital and Emeritus Professor of Clinical Surgery in University College, London. Twelfth Edition. Revised by Hilton Pollard, F.R.C.S., Surgeon to University College Hospital. Cloth, \$1.50 net. Philadelphia: P. Blakiston's Son & Co.

**A PRACTICAL TREATISE ON MATERIA MEDICA AND THERAPEUTICS,** with Especial Reference to the Clinical Application of Drugs. By John V. Shoemaker, M.D., L.L.D., Professor of Materia Medica, Pharmacology, Therapeutics, and Clinical Medicine and Clinical Professor of Diseases of the Skin in the Medical-Chirurgical College of Philadelphia. Fifth Edition, Thoroughly Revised. Pages viii+1143. Size, 9½x6½ inches. Extra Cloth, \$5.00 net. Philadelphia: P. A. Davis Co. 1901.

**REGIONAL ANATOMY OF THE HEAD AND NECK. A Text-Book for Students and Practitioners of Dentistry.** By William T. Eckley, M.D., Professor of Anatomy in the Chicago College of Physicians and Surgeons, etc., and Corlume B. Eckley, M.D., Professor of Anatomy, Chicago School of Anatomy and Physiology, etc. In One Octavo Volume of 210 Pages, with 36 Engravings and 20 Full-page Colored Plates. Cloth. Price, \$2.50 net. Philadelphia and New York: Lea Brothers & Co.

## The Public Service.

### Navy Changes.

Changes in the Medical Corps of the Navy, for week ending Jan. 4, 1902:

Asst.-Surgeon R. C. Holcomb, detached from duty with the Marine Battalion, Cavite, P. I., and from the *Helena*, and ordered home to wait orders.

Asst. Surgeon R. M. Young, detached from the *Constellation*, and ordered to the Asiatic Station, via the *Rainbow*, as the relief of Asst. Surgeon R. C. Holcomb.

Asst. Surgeon J. B. Buchanan, detached from the *Columbia* and ordered to the *Constellation*.

Asst.-Surgeon E. M. Blackwell, ordered to the *Columbia*.

Asst.-Surgeon A. M. Fauntleroy, detached from the Naval Academy and ordered to the Naval Hospital, Norfolk, Va.

Asst. Surgeon P. E. McDonnold ordered to the Naval Academy.

### Marine Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended January 2, 1902:

Surgeon J. M. Gassaway, granted leave of absence for five days from December 26. Granted two days' extension of leave of absence, Dec. 31, 1901.

Surgeon Fairfax Irwin, granted leave of absence for seven days from December 27.

Surgeon P. W. Mead, upon being relieved by Surgeon D. A.

Carmichael, to proceed to Pittsburg, Pa., relieving A. A. Surgeon R. C. Craig.

Surgeon D. A. Carmichael, upon being relieved by P. A. Surgeon H. S. Cumming, to proceed to Vineyard Haven, Mass., relieving Surgeon P. W. Mead.

Surgeon P. C. Killoch, upon being relieved by Asst.-Surgeon J. T. Burkhalter, to proceed to Washington, D. C., and report for orders, preliminary to going to Portland, Me.

P. A. Surgeon J. O. Cobb, granted leave of absence for twenty days from January 2.

P. A. Surgeon H. S. Cumming, directed to assume command of the San Francisco quarantine station, relieving Surgeon D. A. Carmichael.

Asst.-Surgeon Talliaferro Clark, granted leave of absence on account of sickness for seven days from Dec. 15, 1901. Granted twenty-one days' extension of leave of absence on account of sickness, from December 26.

Asst.-Surgeon C. H. Lavinder, granted leave of absence for two days.

Asst.-Surgeon J. T. Burkhalter, relieved from duty at Mobile, Ala., and directed to proceed to Gulf Quarantine Station, relieving Surgeon P. C. Killoch.

A. A. Surgeon D. F. Dudley, department letters of Oct. 10, 1901, granting A. A. Surgeon Dudley leave of absence, on account of sickness, for thirty days from October 7; and leave of absence for thirty days from November 7, amended so that the sick leave shall be from October 9, and annual leave from November 28. Directed to proceed to Immigration Depot, New York, N. Y., and report to Surgeon G. W. Stoner for duty.

A. A. Surgeon R. E. Eberole, granted leave of absence for three days from December 31, under paragraph 181 of the regulations.

A. A. Surgeon H. C. Sibre, granted leave of absence for seven days from December 30.

### BOARD CONVENED.

Board convened to meet Jan. 6, 1902, at the marine hospital, Chelsea, Mass., for the physical examination of an applicant for appointment in the Revenue Cutter Service. Detail for the Board: Surgeon Fairfax Irwin, chairman; Asst.-Surgeon M. W. Glover, recorder.

### Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended January 4, 1902.

#### SMALLPOX—UNITED STATES.

California: San Francisco, Dec. 15-22, 9 cases; San Pedro, Dec. 7, 1 case, origin Handsburg, Cal.  
Indiana: Evansville, Dec. 21-28, 5 cases.  
Kentucky: Lexington, Dec. 21-28, 4 cases, 2 deaths.  
Louisiana: New Orleans, Dec. 21-28, 1 case.  
Maine: Portland, Dec. 21-28, 1 case.  
Massachusetts: Boston, Dec. 21-28, 27 cases, 8 deaths; Cambridge, Dec. 21-28, 1 case; Fall River, Dec. 21-28, 1 case; Medford, Dec. 21-28, 1 case; Quincy, Dec. 21-28, 4 cases; Woburn, Dec. 15-21, 1 case.  
Minnesota: Minneapolis, Dec. 15-28, 22 cases; Winona, Dec. 15-21, 3 cases.  
Missouri: St. Louis, Dec. 19, 1 case.  
Nebraska: Omaha, Dec. 21-28, 20 cases.  
New Hampshire: Nashua, Dec. 21-28, 1 case.  
New Jersey: Camden, Dec. 21-28, 16 cases, 3 deaths; Newark, Dec. 21-28, 20 cases, 6 deaths; Passaic, Dec. 15-28, 4 cases, 1 death.  
New York: Dec. 21-28, Binghamton, 1 case; New York, Dec. 21-28, 19 cases, 4 deaths.  
Ohio: Ashtabula, Dec. 21-28, 1 case; Cincinnati, Dec. 20-27, 9 cases.  
Pennsylvania: Hazleton, Dec. 24-31, 11 cases; Lebanon, Dec. 21-28, 35 cases; Norristown, Dec. 21-28, 5 cases; Philadelphia, Dec. 21-28, 79 cases, 19 deaths.  
Rhode Island: Providence, Dec. 21-28, 1 case.  
South Carolina: Greenville, Dec. 15-21, 2 cases.  
Tennessee: McMinn County, Dec. 15, 24 cases; Memphis, Dec. 21-28, 2 cases; Polk County, Dec. 15, 4 cases.  
Utah: Salt Lake City, Dec. 21-28, 2 cases.  
Wisconsin: Green Bay, Dec. 22-29, 10 cases; Milwaukee, Dec. 21-28, 2 cases.

#### SMALLPOX—FOREIGN.

Belgium: Ghent, Dec. 7-14, 5 deaths.  
Brazil: Pernambuco, Nov. 1-30, 130 deaths; Rio de Janeiro, Nov. 10-24, 119 deaths.  
Canada: Halifax, Dec. 21-28, 11 cases, 1 death; Quebec, Dec. 15-28, 56 cases; Winnipeg, Dec. 15-21, 2 cases.  
Colombia: Cartagena, Dec. 9-15, 2 deaths. Panama, Dec. 16-23, 15 cases.  
France: Lyons, Nov. 30-Dec. 7, 1 death; Paris, Dec. 7-14, 8 deaths.  
Great Britain: London, Dec. 7-14, 506 cases, 29 deaths.  
Mexico: Merida, Nov. 23-30, 1 case.  
Russia: St. Petersburg, Nov. 30-Dec. 7, 4 cases, 4 deaths; Warsaw, Nov. 23-30, 2 deaths.  
Spain: Corunna, Dec. 7-14, 1 death.

#### YELLOW FEVER.

Brazil: Rio de Janeiro, Nov. 10-24, 3 deaths.  
Mexico: Merida, Nov. 23-30, 1 death; Vera Cruz, Dec. 14-21, 10 cases, 9 deaths.  
West India: St. Lucia, Dec. 16, present.

#### CHOLERA.

Java: Batavia, Nov. 16-23, 21 cases, 15 deaths.  
Straits Settlements: Singapore, Nov. 8-16, 10 deaths.

#### PLAGUE—UNITED STATES AND INSULAR.

California: San Francisco, Dec. 15-22, 1 case.  
Hawaii: Honolulu, Dec. 11-14, 4 deaths.

#### PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, Nov. 10-24, 23 deaths.  
Mauritius: Mauritius, Nov. 28-Dec. 5, 52 cases, 37 deaths.  
South Africa: Massell Bay, Nov. 23-30, 5 cases; Port Elizabeth, Nov. 23-30, 1 case.

### THE DIAGNOSIS OF SMALLPOX.\*

JAY F. SCHAMBERG, A.B., M.D.

Professor of Diseases of the Skin, Philadelphia Polyclinic and College for Graduates in Medicine; Assistant Attending Physician to the Municipal Hospital for Infectious Diseases.

PHILADELPHIA.

During epidemics of smallpox the anticipatory attitude of the physician's mind will often lead him to suspect as variola diseases which bear only a superficial resemblance to it. Contrariwise, in the absence of epidemic prevalence of smallpox, mild cases are apt to be overlooked. The latter error is much the more serious in its consequences, although the former may itself lead to embarrassing complications.

The detection of smallpox in its pustular stage, particularly in well-marked eruptions, is a facile matter even for the merest tyro in medicine. The picture of a profuse pustular variola can scarcely be mistaken for anything else. The diagnosis of the disease, however, in the first or second day of the eruption in mild cases, and especially in the absence of an epidemic, may present perplexities. Before the appearance of the eruption the diagnosis is difficult and often impossible. It may be surmised, but it is seldom safe to affirm anything beyond a strong suspicion. The writer recently saw an unvaccinated young man who was suddenly taken ill with fever, headache, backache, chills, vertigo and vomiting—a syndrome perfectly characteristic of the initial stage of smallpox—yet the patient did not develop the latter disease.

There is some variability in the character of the initial symptoms of smallpox. The symptom which most frequently announces the onset of the disease is a chill. This may be severe, accompanied by chattering of teeth, or it may consist merely of a succession of creepy sensations. In many patients the initial symptom complained of is headache. This is often referred to the frontal region and may be of an excruciating character. At other times it is moderate and in mild cases may be entirely absent. In still other cases severe and persistent vomiting is the first manifestation. In such patients the diagnosis of acute gastritis has occasionally been made. The vomiting may be accompanied by diarrhea. Some patients describe the earliest symptoms as general muscular and joint pains with, especially, involvement of the knees.

Some cases begin with severe backache and weakness of the lower extremities. Backache, however, is an inconstant symptom and is perhaps absent in 30 or 40

per cent. of cases. It is said to be more frequently present in severe than in mild cases, and in hemorrhagic smallpox it is apt to be violent in intensity. Very many patients, even in mild attacks, complain of vertigo; this is particularly manifest upon the patient's assuming the vertical position. Some patients, during the last days of the period of incubation, develop a more or less sudden loathing for food, and this complete anorexia may continue for some days. The initial fever may reach 104 or 105 even in cases which prove to be mild. High temperature is apt to be accompanied by delirium and in children by convulsions.

The above prodromal symptoms vary greatly in intensity. In unvaccinated cases they are usually severe. On the other hand, in mild cases the symptoms may be so insignificant as barely to attract the patient's attention. In the vast majority of cases a fairly satisfactory history of the initial symptoms will be volunteered by the patient. In other cases close and specific interrogation of the patient will often recall to him forgotten symptoms.

In an analysis of the initial symptoms in 100 cases recently admitted to the Municipal Hospital the various manifestations were present in the following percentages: Headache was present in 86 per cent.; chills were present in 78 per cent.; backache was present in 70 per cent.; vertigo was present in 57 per cent.; vomiting was present in 55 per cent.; nausea without vomiting was present in 10 per cent. more of cases. In but two patients was there complete absence of an initial stage.

Information as to exposure to smallpox and the character of the patient's vaccine condition are important factors in an early diagnosis. Too often the importance of the knowledge imparted by the character of the vaccination scar and the date of the vaccination is underestimated. If a patient presenting suspicious symptoms of smallpox shows a typical scar from a vaccination performed within a few years, this constitutes strong presumptive evidence against smallpox.

During the initial stage smallpox may be confounded with typhoid fever, meningitis, influenza, typhus, scarlet fever, measles, etc. A number of patients during the present epidemic were suspected during the initial stage of having *typhoid fever*, and the closely scrutinized abdomen exhibited what was at first thought to be "rose spots," but which later proved to be variolous papules. The sudden onset of high fever, the tendency to vomiting and the well-marked backache will usually cause one to suspect something other than typhoid fever. However, in atypical cases the symptoms may be strongly suggestive of the above-mentioned disease.

Both variola and meningitis may be characterized by intense headache, vertigo, vomiting, delirium, coma and convulsions. Without localizing symptoms the latter

\* Read in substance at the meeting of the Northern Branch of the Philadelphia Medical Society, Dec. 19, 1901. For discussion see Society Proceedings.

disease might for a few days be difficult to exclude. *Influenza* may closely simulate the early symptoms of smallpox and indeed time may be the only factor to differentiate the two diseases.

The true eruption of smallpox is occasionally preceded by a prodromal rash which may be morbilliform, scarlatiniform or purpuric in character. These usually make their appearance about the second day of the initial symptoms, but may occur either earlier or later than this period. The purpuric form consists, as a rule, of small pinhead-sized petechiae, often closely crowded together upon an erythematous base, and occupying as favorite regions the lower part of the abdomen, the genitalia and the upper parts of the thighs. The morbilliform and scarlatiniform eruptions may also occupy these regions or may be diffusely scattered over the body surface. Welch states that these rashes have, in his experience, occurred more frequently in varioloid than in severe smallpox. Recent observation of a dozen or more such eruptions tends to confirm this view.

The morbilliform rash may be mistaken for measles, with which eruption it has much in common. I am inclined to think that, as a rule, there is less elevation of this eruption than in that of measles, the finger passed over it often failing to detect the maculae. The rash ordinarily disappears in from twelve to twenty-four hours. Measles may also be confounded with the beginning true variolous eruption. These lesions are, however, smaller than those of measles, are never shotlike, and are disproportionately profuse on the face and hands. There is absence of the catarrhal symptoms affecting the bronchi, nose and conjunctiva; absence of the more or less characteristic lesions of the buccal mucous membrane, and furthermore a remission of the febrile symptoms on or shortly after the appearance of the eruption. The last-named phenomenon and the absence of early tonsillar and throat symptoms will help to distinguish smallpox from *scarlet fever*.

In the eruptive stage smallpox may be confounded with chicken-pox, syphilis, impetigo contagiosa, pustular acne and drug eruptions.

*Differential Diagnosis.*—Smallpox may be distinguished from chicken-pox by attention to the following data:

1. Prodromal symptoms: Fever, headache, backache, chills, vertigo, nausea, etc., occur two or three days before the outbreak of the variolous eruption. In exceptionally mild cases, however, these may be slight or even absent. In chicken-pox the fever and the eruption appear practically synchronously. The constitutional symptoms are more severe in smallpox.

2. Distribution of eruption: In smallpox eruption involves with predilection face, arms, hands and legs; upon the trunk the lesions are more sparse. In chicken-pox the eruption is most profuse, as a rule, upon the trunk, chiefly the back. Smallpox prefers the exposed surfaces, chicken-pox the covered.

3. Character of the lesions: In smallpox they begin as firm, "shotty" papules, which slowly increase in size and develop into vesicles and pustules. Vesicles are uniform in size and often show umbilication. They are multilocular and difficult to rupture with the finger-nail. Chicken-pox lesions begin as "dewdrop-like" vesicles which have a velvety feel. They are unilocular, thin-roofed, can be easily ruptured with the finger-nail, and vary greatly in size.

4. Manner of eruption: Chicken-pox eruption comes out in successive crops, and the lesions may be seen in

varying stages of development. Smallpox eruption comes out in a single crop and the lesions remain uniform in character. Smallpox lesions undergo a gradual evolution from papules to crusts in the course of eight to ten days. Chicken-pox lesions last one or two days and then crust. In the mild smallpox epidemic of 1898 the lesions matured more rapidly than in the old-time smallpox, but the course of the eruption was nevertheless much longer than in varicella. The extent of the eruption is no absolute guide in the differential diagnosis. Severe cases of varicella may look far more formidable than mild cases of variola. The writer has seen undoubted smallpox in unvaccinated individuals, with but two or three lesions present, and the general symptoms correspondingly mild.

The *pustular syphilid*, particularly that variety known as the *variolaform syphilid*, may at times present a striking resemblance to smallpox, and may require careful study to be differentiated therefrom. During epidemics of smallpox such cases are frequently regarded as variola. These pustular eruptions are not always the first cutaneous manifestations of the disease, but often follow upon the macular or papular syphilids. They may occur about the second month to the first and second year of the disease. They are more common in negroes than in whites, and in the debilitated and undernourished than in robust individuals. In syphilis one may obtain information concerning the initial lesion and perhaps an antecedent eruption; also the presence or former existence of mucous patches, alopecia, tonsillar ulceration, iritis, remains of chancre, etc. In smallpox there may be a history of exposure to the contagion of variola.

*Prodromal symptoms:* This complex of symptoms is well marked in smallpox two or three days before the appearance of the eruption. In the *pustular syphilid* there may be moderate fever and general aches and pains preceding by several weeks the outbreak of the eruption. On the one hand there is no such remission of the febrile symptoms on or shortly after the appearance of the cutaneous efflorescence as is seen in smallpox, and on the other hand the constitutional disturbance during the prodromal period and later during the eruptive stage is much less severe and prostrating. Patients with a *pustular syphilid* are not apt to seek their beds.

*Eruption:* The syphilitic eruption comes out in successive crops; it may or may not be more extensive upon the trunk than upon the face. The papules are often firm, but are apt to acquire vesicopustular summits rather than become vesicular or pustular in their entirety. They never progress to those large, full, deep-seated pustules which are so characteristic of variola. The vesicopustules dry into small, brownish crusts, which when cast off disclose to view infiltrated, elevated papules or at times exulcerated bases. Often a little epidermal collarette is seen, showing beginning desquamation of the base of the lesion. The lesions are not invariably uniform in size, and often papules and pustules are interspersed. Occasionally there is a tendency to grouping, which is best noted about the alæ of the nose, commissures of the mouth, border of the hair, etc. The palms of the hands and soles of the feet which are so constantly beset with lesions in smallpox are rarely attacked in the pustular variety of syphilis. In six cases of *variolaform syphilid*, the writer has seen palmar lesions in but one case, and in this patient a solitary vesicle was seen upon the thenar eminence.

This is quite in contrast with many other eruptions of syphilis, which are commonly seen upon the palms. The eruption of syphilis, as a rule, pursues a distinctly slower course than that of smallpox. The itching which is sometimes present in variola is usually absent in syphilis.

Despite these differentiating symptoms, there occur at times cases which defy even the experienced eye to make an immediate diagnosis. Observation of the patient for a few days will disclose the true nature of the disease.

A confounding of smallpox with *impetigo contagiosa* can come only from a misunderstanding of the nature of the latter disease, which is a purely local dermatosis resulting from inoculation of the skin with pyogenic micro-organisms. The eruption is usually limited to the face or the face and hands, and is particularly common in children. The lesions do not, as a rule, exceed a dozen in number, and general febrile symptoms are of great rarity. The lesions are from the outset thin-roofed vesicles or blebs, which rapidly become turbid and dry into yellowish flat crusts. These are cast off in the course of a week, leaving a faint reddish stain. The vesicopustules are extremely superficial and flat and not at all infiltrated. The affection is both contagious and auto-inoculable by contact, and is particularly common in children.

Extensive *papular and pustular drug eruptions* at times simulate smallpox, but may usually be differentiated by the absence of the characteristic constitutional and local symptoms of the latter disease.

Mild cases of varioloid exhibiting but a few papulopustules about the face may bear a close resemblance to *acne*. The history of exposure, the existence of an initial stage and the normal evolution of the lesions will usually enable one to arrive at a correct diagnosis.

The same data are of differential importance in excluding papulo-pustular eruptions occasionally produced by ingestion of the iodids and bromids.

In conclusion it may be stated that it is injudicious to base a diagnosis of smallpox upon any one symptom. A case must be viewed in all its aspects and a diagnosis made from the *ensemble* of symptoms.

## VACCINE VIRUS—ITS PREPARATION AND THE COMPLICATIONS ATTENDING ITS USE.\*

JOSEPH MCFARLAND, M.D.

Professor of Pathology and Bacteriology in the Medico-Chirurgical College.

PHILADELPHIA.

The history of vaccination and its adoption as a prophylactic measure are too well known to need repeating here. The evolution of the vaccine virus is, however, another matter, on which a striking lack of information seems to exist among some of the most practical members of the profession, and I feel that in addressing you upon this subject I may arrange the matter in a new and suggestive form for your subsequent reflection if I contribute no new facts to your store of knowledge.

1. *The Relation of Vaccinia to Variola*.—This has been the subject of arguments from the very inception of Jenner's theory that cowpox protected against smallpox, and there is still some lack of uniformity in the opinions of different writers. Without entering into details, the relationship stands somewhat as follows:

A century ago, when everybody expected at some period of his life to have smallpox, and smallpox was more or less prevalent all the time, outbreaks of the disease among men were accompanied by occasional outbreaks among the domestic animals of peculiar affections, usually of a vesiculo-pustular form, not seen at the present time with any frequency. These diseases of the domestic animals—cowpox, sheep-pox, etc.—usually occurred at times when smallpox was active in the community, though they occasionally occurred spontaneously and may rarely do so at the present time. The vesiculo-pustular course of these affections, and the partial resemblance which the lesions bore to those of smallpox, gave them their names, sheep-pox, cowpox, etc., though I am not aware that before the time of Jenner very much consideration was given them.

You are all familiar with the current opinion of the day that having cowpox protected against smallpox and the experimental way in which Jenner went about proving the truth of the statement, so I will pass over this historic matter to take up the experimental aspect of the subject.

If cowpox is smallpox in the cow, we should be able to produce it at will by inoculating cows with the virus of smallpox. When the attempt to do this is made, however, failure to produce smallpox usually results. The variolated animal usually shows no reaction following such an inoculation, or there forms upon the udder a small nodular swelling without any of the typical characteristics of cowpox. If a drop of serum be squeezed out of this enlargement and transferred to a human being, he becomes variolated; if it be transferred to another cow, it produces an identical lesion. Occasionally, however, such a transfer of variolous matter is followed by the formation of a typical cowpox vesicle which readily infects other cattle, and also produces vaccinia in man. Jenner knew that cowpox seldom resulted from the variolation of heifers, and believed that the best way to originate the cowpox was to inoculate a heifer with the matter secured from horsepox or "grease," which would start it very well. When once the cowpox was secured, its propagation upon cows or human beings was unattended with difficulty of any kind.

We must now inquire why, if cowpox and smallpox are so closely related to one another, there should be such difficulty in originating the one affection from the other, and to explain it we must resort to the known facts of immunity in regard to other diseases. We find certain animals to be susceptible to diseases common to their own kind, partially susceptible to diseases of animals of related kinds, rarely susceptible to diseases of very different kinds. We find that the susceptibility of animals is not only subject to this generic or family variation, but that there is some variation among animals of the same kind.

We also know that micro-organisms vary in their virulence so that they most successfully infect those animals in which they are accustomed to grow, often failing to develop, or developing under such abnormal conditions in other animals that their manifestations are entirely changed.

When we come to apply these principles to vaccination we find that the germ of smallpox develops best in man and that smallpox is, par excellence, a disease of man. We find that some of the lower animals, if brought into intimate contact with human smallpox, acquire disease which may or may not closely resemble it. Thus, mon-

\* Read at the meeting of the Northern Branch of the Philadelphia Medical Society, Dec. 19, 1901.

keys suffer from "monkey-pox," which they acquire by contact with smallpox, and which is somewhat like it; sheep acquire *orinta* or sheep-pox, which is much less like it; horses' "grease," or horsepox, which is still less like it, and cows *vaccinia*, or cowpox, which is a local disease of the teats and udders.

We find that whereas all of these diseases may appear spontaneously in the lower animals, sometimes associated with smallpox of men, sometimes independently of it, it is very difficult to produce them experimentally because we are endeavoring to make a micro-organism pathogenic chiefly for men, grow in animals which under normal conditions resist it. The occasional successes attending the experiments, and the occasional spontaneous occurrence of the affection being accounted for as the accidental infection of animals which happen to be below the average in their vital resistance.

We know that when once the disease is established, its propagation is easy, and that its character is so changed that when the germs are returned to the human being they cease to produce variola or smallpox, but continually produce *vaccinia* or cowpox. Why is this?

The only explanation for it is that the development of the germs in the new soil is attended by such difficulty that they become modified or subjected to permanent biological changes by which their original pathogenesis is lost. Such modifications, or rather, somewhat similar alterations of virulence are matters of everyday experience in the laboratory of bacteriology.

We find, therefore, that the facts of the case are thoroughly in accord with those of immunity, especially when we add that when the variolous material with which *vaccinia* is to be started in a cow, is first made to pass through a monkey, it becomes prepared or modified so that its growth in the cow usually succeeds the very first time instead of only after repeated attempts.

2. *Why should Vaccinia protect against Smallpox even though their Ancestry be the same?*—It is a fact common to all of those infectious diseases which leave immunity behind them, that mild attacks afford immunity which may be as complete and as permanent as serious ones. The original prophylactic measure against smallpox, the "inoculation" or "variolation," introduced into western Europe in 1718 by Lady Montague, wife of the British ambassador to Turkey, was based entirely upon the fact that a mild attack of smallpox was protective against the most serious possible infection. Variolation consisted in the actual inoculation of smallpox matter into the patient. In order that the attack might be as mild as possible, it was performed, if feasible, only when the individual was in the best possible health, and with matter taken from some exceedingly mild case of smallpox. The usual effect was a mild attack of the disease, but it was smallpox, and the patient sometimes died instead of becoming immune, and was always a source of infection to those about him; hence this could not be regarded as a very favorable mode of prophylaxis and was later quickly superseded by vaccination.

It is another fact of immunity that modified germs of disease, or even the toxic products of their metabolism can be followed by protection against their more active fellows.

It was this principle that Pasteur used in his protective inoculations against anthrax, and which Arloing, Cornevin and Thomas employed in protecting animals against black-leg. In the former case the anthrax bacilli were attenuated by heat until their dangerous-

ness was so lessened that they could be introduced into animals without harm; in the latter case the bacilli were attenuated by drying. In both cases the results were the same, and the introduction of the modified germ into the healthy animal was succeeded by an immunity to the virulent organism.

Vaccination rests upon this foundation. The germs of smallpox, by being compelled to grow in the cow, have lost some capability of which they were formerly possessed and by which they were able to disseminate themselves throughout the body and produce variola, and are obliged because of this loss to grow locally and produce *vaccinia*, but the change induced in the body by the progress of the vaccine disease is sufficient to protect it in the future against the unmodified variola germ.

3. *Human Virus, its Advantages and Disadvantages.*—The original vaccinations were all made with virus secured from the pustule upon a human being, and propagated from human being to human being. This method is said to possess two advantages: 1, the vaccinations commonly "take;" 2, the immunity secured is more permanent than that secured by the employment of any other kind of vaccine.

Against these advantages, to which the older practitioners cling tenaciously, is the very serious disadvantage that satisfactory and safe material is very hard to secure, and in the event of a bad selection of material being made, the danger of inoculating some other and more serious disease than *vaccinia* is great. We read of terrible disasters in the past being caused by accidents of this kind, all the children of a certain village in France having on one occasion been inoculated with syphilis in this way.

It is well known that micro-organisms exist in immense numbers in the human scab, and that they are not all harmless. It is a principle of bacteriology that when micro-organisms are frequently transplanted from animal to animal of a kind for which they are pathogenic, their virulence rapidly increases and their manifestations intensify. Thus it comes about that when a few cocci, that under ordinary conditions are harmless or mildly pathogenic are contained in a scab used to vaccinate a child, they grow better in this child than in the former child and produce an exaggerated lesion. When transplanted once or twice more, they become still more virulent until they ultimately become able to occasion abscess, phlegmon, erysipelas, septicemia and even death. Thus, through purely natural means what is a comparatively insignificant operation may by the transmission of various micro-organisms pathogenic for human beings, become a source of the gravest danger. Such dangers certainly outweigh either the advantages of the certain "takes" or more permanent immunity, and it is truly gratifying that at the present time the old method has been abandoned for the newer bovine virus.

4. *Bovine Virus.*—The continuous propagation of vaccine virus from heifer to heifer is said to have originated with Negri of Naples about 1842, and to have required about forty years for its advantages to be so widely appreciated as to permit its introduction into most of the European countries and our own as well.

The advantages of the bovine virus are almost beyond dispute. The *vaccinia* is kept growing in animals for which it is natural, and in which it can be supposed to maintain its most natural degree of virulence. It is secured from animals whose healthy condition can be

determined beyond any doubt, and from animals in which the dreaded human diseases can not occur. The micro-organisms contained in the bovine virus are nearly all of forms which produce no disease of man. There is no possibility of the transmission of syphilis, and no probability of erysipelas, gangrene, septicemia or other of the affections referable to human virus.

**PREPARATION:** In every well-regulated vaccine establishment some modification of the following routine is carried out: Small calves or heifers are received in a special part of the establishment and subjected to a careful toilet. They are curried and brushed, the hoofs trimmed and the feet washed. The entire skin is then washed very thoroughly, a disinfectant usually being employed, then washed out with sterile water. After remaining until the time for operation in a warm stable, they are next taken to a modern operating room, strapped to a table, and shaved over both thorax and abdomen. The skin is washed with soap and water, then with a disinfectant solution, and finally with sterile water, after which the hairy parts are covered with sterile towels and the denuded skin dried. Scarifications more or less extensive, according to the taste of the operator, are next made through the superficial layers of the skin, no blood being drawn, and the virus is rubbed into the scarified area with a spatula.

After this the animal is transferred to the hospital of the institute to await the development of the vesicles. Scrupulous cleanliness must be observed in the hospital, and the temperature should be carefully taken and every precaution adopted to keep the calf well and its lesions free from secondary infection. After the lapse of about six days the vesicles are "ripe" and along the lines of scarification elevated grayish-yellow vesicles covered with macerated epithelium appear. When ready for the removal of the pulp, the calf is again taken to the operation room, placed on the table, given a thorough toilet, and dried. The operator then removes the "pulp" covering the vesicles with a moderately sharp curet, again being careful to draw no blood. The material thus collected is the "vaccine pulp." Different producers employ different methods in utilizing this material. Some reject all the superficial material as unfit for use and collect the clear lymph which subsequently exudes, but the majority use the pulp itself, either spreading it upon points or mixing it with glycerin.

It is evident to anyone possessed of even a small amount of bacteriological knowledge, that in spite of the precautionary measures mentioned, it must be impossible to secure sterile pulp. Indeed, every vaccine contains three classes of micro-organisms: 1. Those specific for vaccinia. 2. Those normally living upon the skin of the animal. 3. Those accidentally entering from the dust of the stable. As a rule, all forms are harmless, but it is only those of the first class that are desirable, for whether they are usually harmless or not, it is doubtful whether any well-informed physician of the present time would prefer to introduce into his own tissues or those of his patients any unnecessary micro-organisms.

**IVORY POINTS AND GLYCERINIZED VIRUS:** The ivory point, spread with the pulp or with the exuding lymph below it is a device which was so far superior to the "scab" that it met with a world-wide reputation and approval, but it is subject to disadvantages that must be mentioned now that still better preparations are before us. The ivory point is spread with matter rich in bacteria. It is true that many bacteria are killed by drying, but it seems equally true that most of those clinging to

the ivory remain alive, probable because of the film of albumin with which they are surrounded. At all events, the death of the bacteria takes place so slowly that the vaccine organism itself dies before the bacteria, and they are never gotten rid of.

Seeing this disadvantage, Dr. Moncton Copeman in 1891 devised the method of mixing the pulp with sterile glycerin of first quality, by which the contained bacteria were slowly destroyed, while the vaccine organism, whatever it is, remained alive. Copeman recommended the method in unqualified praise as being the method by which the bacteria can be destroyed and the vaccine organism preserved.

There are great advantages in this method, for it is eminently desirable that the bacteria be destroyed and it is very gratifying to note that the profession is sufficiently awake to these advantages to now demand them.

There are, however, certain disadvantages. The resisting power of the vaccine organism is insufficient to enable it to endure the action of the glycerin much longer than the bacteria, and by the time that the bacteria are destroyed its own vitality is threatened. For this reason, virus is usually placed on sale while it still contains a few bacteria, thus, to a limited extent defeating the very object in view. However, all must admit that it is better to have a few than a great many bacteria in the virus.

Antiseptic viruses are sold by some producers. They are made by the addition of a germicide to the virus, so that the bacteria are destroyed and the vaccine organism uninjured. This form of virus can still be regarded as in an experimental stage.

*The Accidents and Complications of Vaccination.*—These can only be touched upon in a general discussion of this kind. They have been very important and serious in the past, but are few in number and usually unimportant at the present time. During the "human vaccine" period, syphilis, erysipelas, hospital gangrene, abscess, phlegmon, septicemia, pyemia, and numerous other infectious processes were reported.

With the development of the new technic and the general use of "bovine virus," these were all fairly well eliminated, the only survival of such complications being in the practice of careless physicians who forgot that vaccination is a surgical operation and should be performed with all the precautions attending operations, or in patients who wilfully or ignorantly disregard instructions and take no care of the open wound caused by the operation.

The possibilities at the present time, given in what seems to be their order of frequency are: 1, infection from the skin of the patient; 2, secondary infection of the vaccine wound; 3, infection from the virus.

1. The skin of the patient may be infected with various organisms other than the ubiquitous skin cocci and their occasional presence should warn every vaccinator of the necessity of carefully and thoroughly cleansing and disinfecting the skin before operating—the disinfectant, of course, to be carefully removed.

2. The vaccine wound must be protected from contact with the underclothing, fingers, wash-water, dust, etc., lest secondary infection add its effects to the lesion already existing. The satisfactory method of doing this has not yet been devised. In all probability a simple dressing of sterilized gauze will do as well as anything. Shields are to be carefully avoided as being unclean, irritating, obstructing the lymphatic circulation and producing anaërobic conditions suitable for the growth

of pathogenic bacteria such as the tetanus bacillus.

3. The virus itself if not properly prepared, or perhaps occasionally through unavoidable accident may contain infectious organisms. The most important of these are the skin cocci which occasion severe local lesions, and the tetanus bacillus which has done considerable mischief of late.

## REVERSIBILITY OF ENZYMES, AND ITS APPLICATION TO PHYSIOLOGIC AND PATHOLOGIC PROCESSES.\*

H. GIDEON WELLS, M.D.

CHICAGO.

Ordinary chemical reactions with which we are most familiar are usually considered as occurring in a very definite manner, the addition of one substance to another leading to the formation of one or more new substances. But it is also a fact that if the proper conditions are produced such a reaction can be made to take place in a reverse manner, the resulting substance or substances being made to yield the substances from which they were originally produced. Recent work has developed the fact that enzyme action is also capable of reversibility, so that when proper conditions exist the products of the hydrolytic splitting, if such has been the change, are reunited by the same enzyme that separated them into the original, more complex molecule. This newly observed property is probably destined to explain many important problems in physiology and pathology, and as so far the literature dealing with the subject has been quite closely limited to technical chemical publications it has seemed desirable to review the work so far done, and to discuss the speculations into which it leads.

Schmiedeberg<sup>1</sup> had a demonstration of the reversibility of enzymes before him twenty years ago, but while observing the facts he did not interpret them as we now should. He observed not only that renal tissue was able to cause benzoic acid and glyceoll to unite when a mixture of these two substances was brought into contact with it, forming hippuric acid, but also that it was capable equally of splitting hippuric acid into benzoic acid and glyceoll. The splitting of hippuric acid he attributed to a ferment which he succeeded in extracting, and which he called *histozyme*. But he not only did not consider that the histozyme caused the formation of hippuric acid from the two components, but even stated that absence of histozyme was a requirement for this synthesis, which probably was due to some other agency.

The credit for actually appreciating the reversibility of enzyme action belongs to A. C. Hill.<sup>2</sup> He approached the subject with the express purpose of testing the possibility that enzyme action was reversible, as simpler chemical reactions were known to be. As a suitable object for investigation he selected maltose, because each molecule of this sugar is split up by the enzyme *maltase* into two molecules of glucose, and not into two dissimilar molecules as is the case in so many hydrolytic cleavages. It was known that when maltase acts upon maltose in solution a certain amount of the sugar is split up into glucose, but not all of it, so that the result is a mixture of maltose and glucose. Hill found that a similar final result was obtained if the maltase

was added to a solution of glucose, for then some of the glucose molecules united to form maltose. Here again the reaction was never complete, and further investigations showed that if all conditions were made similar the final result in either case was the formation of a mixture of the two sugars with a certain definite proportion of each kind. In other words, the action of the enzyme terminates when the enzyme-containing solution holds a certain definite proportion of each sugar. If placed at first in a solution of this composition it would cause no changes whatever. Thus it is seen that the action of the enzyme is merely to establish an equilibrium, and it accomplishes this by causing either cleavage or union as the need may be.

Such a reaction may be expressed graphically as follows:

The double arrow indicates that the reaction occurs in either direction. The reaction of histozyme might similarly be expressed:

As the enzyme action tends always to bring the solution to an equilibrium, anything interfering with the attainment of an equilibrium will cause a continuance of the action, if needs be, until complete exhaustion of one of the substances. This is what takes place in digestion. The non-absorbable sugar is split up into absorbable sugars which are removed by the circulatory fluids as they pass through the intestinal walls, and as it therefore becomes impossible for an equilibrium to be established, the cleavage continues until all the sugar in the intestine has undergone cleavage and its diffusible products have been absorbed.

### LIPASE.

More recently our knowledge of reversible enzyme action has been enlarged, and its application to biologic problems begun by the valuable work of J. H. Kastle and A. S. Loevenhart<sup>3</sup> of the State College of Kentucky. Their work was done with *lipase*, the fat-splitting ferment of the pancreatic juice. For reasons of technical convenience they utilized ethyl-butyrate, but lipase acts alike on all fats and the results obtained are applicable to the fats of common food and tissues. They demonstrated that lipase is able not only to split up fat into fatty acid and alcohol, but also to unite the two latter to form fat. Like the action of maltase, the direction of the reaction depends upon the establishment of an equilibrium, and the result is always a mixture of fat, fatty acid and alcohol. For all cases, then, lipase action may be represented by this equation:

Through its action on butyric acid and ethyl alcohol they were able to study the occurrence of lipase in places other than the pancreatic juice. It was found to exist widely distributed in the body, in the liver, gastric mucous membranes and kidneys. In fact, the pancreas contains far less active lipase than the liver, at least in the hog, for the results obtained with an extract from the liver were nearly three times as great as a corresponding amount of pancreatic extract gave. Of especial importance, as will be seen later, is their demonstration of the presence of lipase in the mucous membrane of the small intestine. None of the tissues they studied

\* My attention was first attracted to this most interesting subject by the lectures of Prof. Jacques Loeb, of the University of Chicago.

1. Arch. f. Exp. Path. u. Pharm., 1881, xiv, 379.

2. Jour. of the Chem. Society, 1898, lxxviii, 634.

3. Chemical News, 1901, lxxxiii, Nos. 2150 to 2155; and also, American Chemical Journal, 1900, xxiv, 491.

failed to show a considerable lipase activity, but their researches in this direction were not numerous and it remains to be seen if there is any tissue that does not contain lipase. Even if it should be shown that certain tissues are free from this ferment, which is not probable, considering the almost universal distribution of fat, it is certain that no organ is without lipase during life, for Hanriot has shown that blood serum contains a considerable amount of active lipase. However, it is probably quite a different matter whether the ferment is in the cells of an organ or merely in the fluids circulating through it, in so far as its fat metabolism is concerned.

For other enzymes a reversible action is yet to be demonstrated, but there seems no good reason for disbelieving that it is as true for all the others as for histozyme, maltase and lipase. There is much work to be done in this direction, with good prospects for interesting results. Naturally the question suggests itself: If proteolytic enzymes are also reversible may not proteids be synthesized by acting on the products of proteolysis with the enzyme? Certainly if we assume that all enzyme action is reversible many features of metabolic processes become much simplified. And also as recent investigations tend to show the inseparability of all metabolic processes from enzymes, the importance of this added knowledge of the enzyme processes must be apparent. So far as the subject has yet been investigated, however, we are only justified in applying the results to fat metabolism.

#### FAT METABOLISM.

The history of fat in the body may now be considered to be as follows: The lipase in the stomach does not act, because of the presence of hydrochloric acid. In the intestines lipolysis occurs, with production of a mixture of fat, fatty acid and alcohol—usually glycerin. But as the fatty acid and glycerin are diffusible, while the fat is not, they are separated from the fat by absorption into the wall of the intestine. Hence an equilibrium is not reached in the intestine, so the splitting continues until practically all the fat has been decomposed and the products absorbed. When this mixture of fatty acid and glycerin first enters the epithelial cells lining the intestines there is no equilibrium, for there is no fat absorbed with them as such. Therefore the lipase, which Kastle and Loevenhart showed was present in these cells, sets about to establish equilibrium by combining them. As a result we have in the cell a mixture of fat, fatty acid and glycerin which will attain equilibrium only when new additions of the two last substances cease to enter the cell. Now another factor also enters, for on the other side of the cell is the tissue fluid, containing relatively little fatty acid and glycerin. Into this the diffusible contents of the cell will tend to pass to establish an osmotic equilibrium, which is quite independent of the chemical equilibrium. This abstraction of part of the cell contents tends to again overthrow chemical equilibrium, there now being an excess of fat in the cell. Of course the lipase will under this condition reverse its action and split the fat it has just built into fatty acid and glycerin. It is evident that these processes are all going on together, and that as the composition of the contents of the intestines and of the blood vessels varies the direction of the enzyme action will also vary. In the blood serum, and perhaps also in the lymphatic fluid, although this has not yet been investigated, there is more lipase which will unite part of the fatty acid and glycerin, and by removing them from the fluid about the cells favor osmotic diffusion

from the intestinal epithelium, thus facilitating absorption.

Quite similar must be the process that takes place in the tissue cells throughout the body. In the blood serum bathing them is a mixture of fat and its constituents, probably nearly in equilibrium since lipase accompanies them. If the diffusible substances enter a cell containing lipase, *e. g.*, a liver cell, the processes of building and splitting will be quite the same as in the intestinal epithelium. The only difference is that here the fatty acid may be removed from the cell by being utilized by oxidation or some other chemical transformation.

To summarize, it may be stated that throughout the body there is constantly taking place both splitting and building of fat. *Fat enters the cells, leaves them, and is utilized only in the form of its acid and alcohol, never as the fat itself. Fat constitutes a resting stage in its own metabolism.* The description given above agrees with all known features of fat absorption and utilization. For example, the crowding of the epithelial cells of the intestinal mucosa with minute fat droplets during digestion is now explained as the result of lipogenesis. That fat can be absorbed in the emulsified state, as the older physiologists considered these droplets indicated, seems physically improbable. Such a conception is now no longer necessary. The fat depots throughout the body serve to maintain the supply to the blood, and contain lipase which here, as elsewhere, maintains an equilibrium.

If proteolytic\*\* enzymes are also reversible, then the phenomena of proteid metabolism are similarly explained. It has long been known that between the time peptones and albumoses escape from the intestines and enter the circulatory fluids they are changed back into proteid. This fact decidedly supports the conception that an enzyme exists in the intestinal epithelium, acting reversibly on proteids just as the lipase does on fats. There is sufficient evidence to assume that so-called proteolytic ferments also are generally distributed throughout the body. Pepsin has been positively demonstrated in muscles, and Salkowski and Jacoby have called attention to a form of self-digestion which occurs in the tissues during life and also after death, termed *autolysis*, in which the chemical nature of the products of the change indicates a relation to tryptic digestion.

*All metabolism, then, may be considered as a continuous attempt at establishment of equilibrium by enzymes, perpetuated by prevention of attainment of actual equilibrium through destruction of some of the participating substances by oxidation or other chemical processes, or by removal from the body or entrance into it of materials which overbalance one side of the equation.* The living body, whether unicellular or multicellular, is a vast, unceasing series of chemical reactions.

#### FATTY METAMORPHOSIS.\*\*\*

Applying this fact of reversibility of enzymes to the subject of fatty metamorphosis, so-called, some interesting criticisms of recent literature may be made. Very recently C. Hester<sup>4</sup> made a study of "fatty degeneration" based upon the attempts of some investigators at the Rostock Institute to explain it as due to an increased saturation of the degenerated tissues with fluids from

\*\* The term "proteolytic enzyme" will need to be replaced if it is shown that the enzymes usually referred to under that title have equally splitting and building functions. The general term "protease" might be satisfactory.

\*\*\* The subject of fat necrosis will not be considered at this time, pending the results of certain experiments now incomplete.

4. Virchow's Archiv, 1901, cxliv, 293.

the blood, the increase in these fluids in turn being due to circulatory disturbances. Hester injected olive oil into the muscles and intermuscular fascia of rabbits. It disappeared very quickly from the vicinity of normal active muscles, more slowly when the muscles were inactive. Such wandering cells as were found passing out from the site of the oil deposits contained but little fat. The muscle fibers near the injected fat showed a fatty deposit as a narrow sub-fascial zone, with some isolated fatty fibers throughout the muscle. Thus it is evident that free fat in the tissues may enter the muscle and fascia cells, and presumably other cells. An exactly similar relation was found between fat depots and fatty muscle fibers under diseased conditions in human beings by investigating fatty hearts, fatty eye muscles, and also muscles in a case of exophthalmic goiter. Here the fatty areolar tissue takes the place of the injected oil of the experiments. From his study of the manner of the transfer of fat from the interspaces into the muscle cells Hester was led to make this statement: "There can be no doubt that the fat enters the muscle fibers in a split condition, and within them is again built up into fat. The splitting of the fat is accomplished in the tissue fluids, the building within the cells." He was familiar with Hanriot's demonstration of lipase in blood serum and quite correctly attributed to it the splitting of the fat in the tissue fluids. He did not know how it was again built up in the cells, but states his confidence that it will ultimately be proven that all the cells of the body, except red corpuscles, are capable of fat synthesis. His explanation is quite complete except that he does not account for the step which lipase takes within the muscle cells.

Hester disregarded the other side of the question of fatty metamorphosis, namely, can proteid be changed into fat? This has been thoroughly threshed over by A. E. Taylor,<sup>5</sup> chiefly from the standpoint of investigations made upon animals by phosphorous poisoning, or by feeding various known fats. He concludes that: 1. Formation of fats out of proteid physiologically has not been demonstrated or made probable. 2. Nor has it been demonstrated under pathologic conditions; there is much evidence against this, and in favor of its being an infiltration or a formation of fats from carbohydrates. In a subsequent publication<sup>6</sup> he reviews his own experiments with frogs poisoned with phosphorous, in which he failed to find any evidence of conversion of proteid into fat.

Of the work in favor of the view that the so-called fatty degeneration is in reality an infiltration, the most striking is that of Rosenfeld,<sup>7</sup> which is quoted by Taylor. This investigator found that starved dogs, when fed on mutton fat, deposited a fat of the same composition as the fat of sheep. If such abnormally fattened dogs were again starved and then poisoned with a drug causing fatty degeneration, phloridzin or phosphorous, it was found that the fat in the degenerated liver was mutton fat. Evidently the fat had been transferred from other tissues to the liver, and was not formed there. Moreover, the liver had lost little of its nitrogen. Another investigation showed that a starved bitch, impregnated, and fed on mutton fat, yielded a milk containing mutton fat. Rosenfeld's results may be looked upon as agreeing with what we should expect to occur through the action of the lipase of the cells and the blood. If a fat rich in stearin is brought to a cell the

lipase will reform it, after dissociation in the blood into a fat of the same composition, irrespective of what fat is most usual in the body of the animal. The reason that each variety of animal has its own type of fat may perchance be sought in a less ready oxidation of that fat, so that it tends to accumulate. After starvation, however, as in Rosenfeld's dogs, when a certain type of fat is provided any accumulation would necessarily at first be of that type.

Rosenfeld may fairly be said to have shown that in poisoning a certain type of fatty change, which is generally considered as "fatty degeneration," in contrast to "fatty infiltration," is really an infiltration. This renders it indeed probable that a similar explanation is to be found for so-called fatty degeneration in other pathologic conditions.

However, it has never yet been shown that proteid can not produce fat, any more than it has been shown that it does do so. If in its catabolism cell-proteid produces fatty acids and alcohol then fat will be produced, since in the cells is a ferment capable of uniting them. This much is new, and it offers a possibility to those who seek to show that fat can be formed from proteid. Still it must be observed that among the known decomposition products of proteids are no fatty acids at all comparable to those constituting the ordinary body fats. The nearest approach is in the amido-acids, such as leucine and glycocoll, but none of these contain nearly as many carbon atoms as do oleic, palmitic and stearic acids. We know as yet no enzyme capable of combining lower fatty acids into higher—certainly there is no reason yet shown for assuming that lipase does so; therefore, if proteid is really a source of fat, there must be other agencies at work than any with which we are yet familiar.

It is to be noted that the organ in which fatty metamorphosis is most often and most extensively seen as a pathologic process, the liver, contains the most lipase, so far as the observations of Kastle and Loevenhart have gone. This is quite comparable with the observation of Loevenhart<sup>8</sup> that the mammary gland during lactation contains much more lipase than when at rest. It seems, then, that the amount of lipase in the cells bears a direct relation to the amount of fat that will be formed in them. This may be explained by the fact that if an equal amount of fatty acid and glycerin is taken into each of two cells containing different quantities of lipase, fat will be formed more rapidly in the one with the greater amount of lipase. As the fluid bathing the cells is continuously moving from one part of the body to another it maintains nearly a constant composition, so that the amount of acid and glycerin that will diffuse into each cell will depend solely upon the amount already within the cell. Obviously the cell wherein the fatty acid and glycerin have been combined into fat will be in condition to receive more new material than will the other in which they are largely ununited, since the entrance of these substances is simply a matter of osmosis. Hence this fat-laden cell will continue to add more and more fat. This may indicate the normal mechanism of fat storage in the areolar tissue depots, which are known to contain considerable lipase.

Shall we consider from this that "fatty degeneration" is simply a matter of quantity of enzyme in the abnormal cells? It surely seems strange that a cell injured by toxic, mechanical, or nutritional agencies should possess any increase in lipogenetic power—on the contrary,

5. Amer. Journal of the Medical Sciences, 1899, cxvii, 569.

one would expect the lipase to suffer with the cell. This seems to be the case. A. Poulain<sup>9</sup> has investigated the lymph glands in health and disease with the following results: 1. In normal conditions the lipolytic power is the same in the mesenteric glands and in the subcutaneous glands at the same time in the same subject. 2. In intestinal infections the lipolytic activity of the mesenteric glands diminishes greatly compared to the peripheral. 3. The contrary relation is found when the infection is in the area draining into the subcutaneous glands. 4. In generalized infections the lipolytic power is lowered about the same in all the glands of the body. In other words, when the glands are injured by toxic substances their power is decreased. But Martin Jacoby<sup>10</sup> has found that autolysis, which is evidently a ferment action, is increased in phosphorous poisoning, and it may therefore be that lipase is injured by some poisons and stimulated by others. Study of lipase activity of livers that have been rendered fatty by phosphorous and similar poisons may yield interesting results.

Another factor must also be considered, namely, the process of removal of fat from the cell. This, so far as we know, is accomplished by oxidation. According to recent investigations this oxidation is also an enzyme action. May it not be, then, that poisons cause fatty degeneration only when they are of such a nature that they destroy the ferments that oxidize the fat, and do not destroy the lipase? Under such circumstances the fat equilibrium in the cell would be established when there was chemical equilibrium between the formed fat and the free components, and an osmotic equilibrium between these diffusible substances within the cells and those in the blood stream. Unlike normal conditions there would be no third factor of removal of fatty acid and glycerin by oxidation; this might lead to an accumulation. As agreeing with this idea are: 1. The fact that only certain poisons cause fatty change. 2. The association of nuclear changes with fatty degeneration, and the demonstrated fact of the importance of the nucleus for processes of oxidation within the cell (Spitzer,<sup>11</sup> Loeb<sup>12</sup>). 3. Besides, as a result of poisoning, fatty change is also a result of circulatory disturbances, as in infarction. Here impaired oxidation is recognized as a factor; and weight is given to this belief by the similarity of the processes in the chronic asphyxia of pernicious anemia and of lung disorders. There is no reason for considering that this fatty change is different from that in poisoning, i. e., they both probably indicate impaired oxidation, the one from absence of oxygen, the other perhaps from lack of enzyme to combine the oxygen. A study of both *lipase* and *oxydase* activity in normal livers and in fatty livers may determine this question finally.

**Treatment of Wandering Spleen.**—Ssaweljew describes in the *Med. Obshcheye* the successful treatment of a wandering spleen in a boy of 4 who had recently recovered from smallpox. The enlarged organ lay in the umbilical region and was painful on pressure, causing almost constant vomiting. There were also symptoms of intestinal catarrh. Treatment was directed first against the enteritis, after which euehinin was administered in order to reduce the size of the spleen. The spleen was restored to its place and maintained in position by a bandage, while the child was kept on his back in bed. A complete cure was thus attained.

## PULMONARY FEARLESSNESS.\*

W. T. ENGLISH, A.M., M.D.

PITTSBURG, PA.

From the earliest records of primitive man there are evidences of a wide range of his fears, and the noble advantages secured through the pedagogy of fear. Ere reason ascended its lofty throne, fear expressed itself through the somatic life, and with a celerity which outruns human thought still continues to protect us against threatening harm, even before we know in what the harmful thing consists. Whether originating in the soma or psyche, and however modified, fear invariably appeals to the sentience of the breathing apparatus and exalts the pulmonary movements beyond the realms of automatism. Those fears which in primeval days prompted directly the exercise of the pulmonary sentience or indirectly necessitated excessive activity of the lungs added to the efficiency of these organs by maintaining and cultivating their primary allotment of somatic and neural energy and became factors in the attainment of normal intercourse between the nerves distributed to the breathing apparatus and the higher centers. Hundreds of generations have regarded the respiratory organs with a reverential awe, which is the outgrowth of fear, and the ancients considered the terms "breath" and "breathing" as etymologic equivalents of "soul" and "spirit." From the very nature of his inheritance, man is at birth a pulmophobic. The first new impulse is inaugurated through fears which are products of primal psychisms and impels the newly born to fill his lungs with air, and as he is but a reflex and automatic organism, these fears gain expression through somatic channels. The teleologic significance of this awakening of the breathing apparatus is emphasized by the oft-repeated and obvious prenatal efforts at self-protection during that portion of gestation within the range of fetal impressionability. This first betrayal of fear influence upon the pulmonary apparatus on the child's advent into independent existence, is repeated thereafter in consequence of each wavering or irregular action of the lungs. Sleeping or waking, fear guards, protects and dominates respiration, as it does no other function. Throughout the early life of those who have their proper legacy of fear, the threatened pulmonary apparatus startles like a guilty thing, as a result of limitations. Even in the semi-consciousness of dreams respiratory modifications cause the most acute alarms.

The normal child regards closed rooms and confinement within small areas as an alienation from safety. Caves, small apartments, narrow passes and dense forests produce fear effects through respiratory restraint. Fogs, gases, odors, mists, smoke, the barometric fall, each may exert an influence detrimental to perfect pulmonary activities with resulting apprehension. A personal acquaintance with fears which concern the pulmonary apparatus has been the early experience of most of us. The plays adopted usually imply the hidden foe springing upon his victim, or the imitative nature assumes the beasts of prey, and, in the simplest outbursts of juvenile enthusiasm there is an instinctive leaning toward the deep, powerful, dangerous primeval sensations, in which the breath comes in great waves or gulps. If the child were born immune to fear, he would be denied part of his pleasure-giving birthright. During childhood, and later in some cases, there is a continu-

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Hygiene and Sanitary Science, and approved for publication by the Executive Committee of the Section.

ance of reflex and automatic organism; and the innate tendencies are best observed while the experiences are yet limited to motory and sensory impressions, and before a wider experience and the influence of environment disguise their true character.

Delicately poised in the realm of sense and possessed of just sufficient sentience to keep them operative without causing needless pain, the perfect lungs assume their office. Influences intrinsic and extrinsic tend to blunt and ultimately overcome this delicate sentience, and thereby interfere with their perfect functioning. In all periods of life the personal factor determines the character, rapidity and extent of the deviations; but these may be modified by the conscious need for prevention, and may be exalted by cultivation. Ignorance of these possibilities results in neglect, and decline in pulmonary sentience is the rule.

It will be noted that in one there is a rapid, and in another a deliberate appearance of pulmonary indifference. In addition to the diminished dynamic energy of the lungs there is a corresponding increase in the self-respect of the organs. They hold other organs in smaller esteem because they are constantly inquiring of them how they are, and the pulmonary apparatus is delegated to a systematic and careful neglect. In most cases the archaic fear promptings subside after eight years of age, with a celerity that is truly alarming to the careful observer. Just about this time in life the mental influences assert themselves and demand some of the attentions which hitherto belonged to the somatic and reflex organism.

The growth which is most important and should consist in augmentation of individual parts of the body, is prematurely intruded upon by a development which is easily objectified and demands a careful solution. It must be remembered, however, in this connection that natural echoes of areadian fears through the lung activities are only reflections of what was in the past generations and an intimation of what might be—not what is.

#### STAGES OF FEAR DECADENCE.

The first stage of decadence then, which we denominate "indifference," succeeds closely upon the resurgence of the primitive fear waves as expressed in the sense repletion of childhood's daring acts and grotesque demeanor. Its sudden subsidence is the natural sequence thereto. These are all belongings of the individual through inheritance. Those influences which have to do with the pulmonary apparatus through environment, and are acquired, are of later origin. The retrocessive movement of the fear wave ceases not, but continues to a wider indifference. There is less spurtiness in the succeeding stages, and the influence toward that degree of somatic and neural delinquency, which we name "lethalization," is usually very insidious and slow, and includes the sentience of nerve centers, as well as the innervation of the organs and the soma. This insidious invasion of the unconsciousness in organs or centers of respiration is aptly illustrated by the frog, which will allow itself to be boiled to death without moving if the heat is applied gradually enough. This unconsciousness is approached so slowly in some, and in all is so variable as to the time of its completion, that it may occur at any period of life. It is most common between pubertal age and maturity. Those of us who withstand detergent influences of these downward steps in the fear obsolescence, may at least be impressed with the fact that after puberty we can have only an acquired interest in pulmonary completeness, and that if perchance the stage

of "lethalization" has passed on to that of "anesthetization," there is vouchsafed to us a fear unconsciousness from which there is no awaking, and which must lead downward to an ingravescent asthenia from whence there is no recall. This asthenia once established grows with the very life it feeds upon. It differs in degree rather than kind, from that of the fearlessness which possesses the mind, nerves and body of the victim of pulmonary consumption, who is deaf, blind and generally senseless to the clangorous harbingers of death, which are obvious to all but himself. Most of us have doubtless noticed that objective signs of pulmonary waste, failing health, and even approaching dissolution, are not only unappreciable to those upon whom tuberculosis has lain its awful hand, but through its delusions it establishes a hopefulness in realms from whence hope is normally banished. Even those subjective symptoms of consumption which would be likely to cause complaining under like conditions in other diseases, are in this disorder anesthetized out of the realm of sense. When special causes have reached so far as to affect the tissues of the blood through oxygen starvation, they guarantee a prolonged neural depletion, which may be observed from the slightest inaction of the nerves to radical depletion of the higher centers. One more step may yet be taken by these pitiless delusions, and bodily increase is supposed to exist where there is evident depletion, augmentation in strength where there is exhaustion, and various other imaginary gains in the presence of losses.

In this connection it must be borne in mind that fear manifestations are exceptional, and can only be expressed through other channels than those once associating the lungs with the ideational centers, and if so expressed will be tainted by entoptic chimeras and can not yield symptomatic intelligence. This false fear uprising is sometimes manifested in the presence of hemoptysis. When organs are deprived of wonted sentience through inheritance, lethalized by indifference and palsied by disease, fears and hopes are alike deceptive—

"Hopes thus belie our fears,  
Our fears our hopes belie."

It has been proven by every method of analysis that the stages of fear obsolescence are a part of the phenomena of lung degeneration.

To complete the symptomatology of pulmonary consumption the stage of pulmonary fearlessness is needful, and it has been regarded so common a factor in this malady that it is empirically associated with the tubercle bacillus. While we may not identify the fearless concept within the field of the microscope, it bears to the lungs as close relations as does the fear impression to the psyche or mind. Such indifference to the evidence of approaching dissolution as that exemplified by consumption, can not be a mere matter of cultivation, for no other malady so completely shuts out fear or so unwarrantably exalts hope as does pulmonary tuberculosis.

The degrees of nervous display and emotional exhibit in lung interest, show the individual relations to the danger line, i. e., in proportion to the shortening of the danger line, the hope tone is exalted; the more ample the danger line, the lower the confidence in pulmonary integrity and the deeper the fear psychoses. Each shortened oscillation is but the lessened expression of the fear element which once was the dominating factor in, and incentive to, human action; and has been a part of the complex of every life since primeval days.

To recapitulate: Fear gives its most natural and wholesome impulse at the termination of child life

through the bodily organism, and it continues, though dimmed and made fainter through the ages, its quiet and persistent influences without our aid until that stage of extinction is reached which presents the other extreme, viz., "fearlessness." Between these two extremes lie the steps qualified by the terms "indifference" and "lethalization." Grafted upon the latter through incidental or concomitant constitutional crises, may be an insane hopefulness more baseless than "the fabric of an empty dream," which deludes the victim to his doom and flatters him to the grave.

#### FEAR IN ITS RELATION TO DISEASE.

It is observed that while the fear diathesis is universal, and will show itself somewhere if circumstances are consistent with and favorable to its display, yet diseases have modifying influences which are more or less constant. This fact was observed as early as the seventeenth century by the noted physician, Phillip Pinel, of whom it is related that he always questioned his patients as to the fear symptomatology.

It may be regarded negative evidence as to the presence of bacilli when the fear manifestations are constant in suspected lung disease, or these emotions may be due to some complications to which the fear symptoms may lay claim. Enduring pulmonary palsies occasioned by interference with the nerve supply essentially concerned in the functional activity of the lungs, are almost certain harbingers of pulmonary degeneration.

Some interesting facts are disclosed by comparisons of fear manifestations, as shown in diseases of unlike character to pulmonary tuberculosis. In disorders of a fear-inspiring nature, there is a seeming antagonism toward and a want of affinity with pulmonary consumption, which appeals to the observer at once. For instance, that awe-awakening and most heavily fear-laden of all known maladies, cancer, is almost never found in association with tuberculosis. Goitre is another disease which is accompanied by excessive fear expressions, and this disorder is as rarely found in combination with consumption as cancer. Nevertheless, goitrous regions abound with tuberculosis, and indeed, there is no zone exempt from it.

Fear-awakening heart disorders and cardiac hypertrophy with increased activity of the respiratory muscles are unfavorable to pulmonary tuberculosis. Emphysema necessitates conscious respiration and does not associate itself with conditions favorable to tubercular deposit. The pregnant woman, becoming so during the process or at the incipency of pulmonary tuberculosis, usually lives a charmed life during gestation, being protected from its ravages until the end of her term, after which the disease takes up its course and continues to a fatal termination. The presence of the child exalts the costal respiratory efforts, and the fears and fright incident to the child's activity and the mother's anxiety for its safety are assumed to have to do with this antagonism.

It is the experience of those who treat chest diseases that tears, or emotional evidences and anxieties do not disturb the real victim of consumption, when applying for an opinion as to his pulmonary condition, whereas the suspected but innocent one displays tremors and fears, which are of diagnostic value. On the other hand, we may note briefly that those maladies which temporarily hold the lungs quiescent, or place them in a kind of paresthetic thrall, are prone to be followed by consumption. This latter disease, however, is not to be found

immediately associated with the active stages of fevers, but appears as one of the sequelæ.

Tuberculosis of the lungs is almost unknown as a concomitant of typhoid fever, but it is a very common secondary affection which appears speedily after the fever has subsided. Diabetes is a quiescent, insidious and unalarming malady, and in this respect resembles tuberculosis; these two diseases are so commonly associated that 50 per cent. of the victims of either malady will show signs of each. Urinalysis is essential in every case of tuberculosis and microscopic investigations of the sputum in cases of glycosuria are also needful. Numerous other illustrations are at hand, but these will suffice to prove that—

"By some of life's sorest ills  
Our fears are first anesthetized."

While this fearlessness grows upon us the successive changes touch us everywhere. Even our sentiments are employed to obscure the plain teachings of cause and effect.

#### THE MORAL PLANE AND SENTIMENTAL ASPECT

of the individual case are made to appear everything which they truly are not. Though in every other direction there may be a moral tone which will prevent man from unwillingly or knowingly making that which is worst in him a distinguishing trait, this principle is not applied in the direction of the lung demeanor. It may be made obvious to each that the fearless lungs are carnal untruths among organs which are universally truthful, and that other organs than those of respiration, if ill, usually take cognizance of the most trifling annoyances and refer them to the centers. Yet there is a self-sufficiency in the pulmonary languor which yields complacency under all circumstances.

The pulmonary candor of our race becomes problematic, when, after pointing out the delinquencies and receiving a confession of shortcomings, they continue. This disposition to pulmonary prevarication dominates not only the mind, but also the action of the individual and gives grotesqueness to the pulmonary proprieties, and each becomes an ally of disease, while professing sincere admiration for those who are in a pulmonary *sense recherché*. There is an universal as well as individual inconsistency.

The lines of pulmonary proprieties rudely separate respiratory sincerity from pulmonary amenities. The instinct of the breathing apparatus is stifled by the tenets of polite pulmonary demeanor. As early as possible the respiratory will is broken and subjugated to the polite habits of the age, and these are usually impressed before many removes from the threshold of life. In the nursery, the child disposed to give evidence of his pulmonary or vocal presence is in danger of social ostracism, or at least is regarded as an unworthy associate of the quiescent prim dignitary with bacilli in his pulmonary apices. The pulmonary pigmy becomes an object of envy in the kindergarten because he is divested of the innate pulmonary and vocal impediments which prove hindrances to the social exaltation of his physical superiors. The feeling of resentment possesses each pulmonary nobleman who has grown out of short frocks into trousers, as he recalls his limitations which only permitted him to be "seen and not heard." Among the elite it is handed down through later years as an axiom that vocal continence and respiratory abstinence are deserving of emulation. Conventional asphyxia adopted early and continued long enough guarantee physical, mental and moral obliviousness to respiratory insincer-

ity throughout later life. Thus, some are unburdened of pulmonary fear and divested of the most rudimentary or primal evidence of lung sentiency. Polite lungs are made to fall short of perfect communication with the ideational centers, and the number of those in whom the reflex arc is not repeated in the respiratory organs is thus augmented. Pulmonary fixidity is substituted for spontaneous diversity for which the lungs are obviously provided. The most vigorous child may thus be forever denied the pulmonary conquest of that which, untrammelled, he might have the innate strength to grasp and to hold. We may appreciate in this view one of the causes which contribute to make the centers of civilization foci of pulmonary indifference, and may better comprehend why countries where refinement is at its zenith yield up their pulmonary integrity. Moreover, it may aid in explaining why young men of pulmonary vigor from the country are usurping the places of the city-bred youths, and passing them in the race towards success and distinction. Those who promote these fallacies do much to counteract the accumulated advantages of hygiene and sanitation. Nature's rule will obtain despite conventionalities, and it provides that, "the relics of psychic states and acts, with their lapsed reflexes and somatic impressions can only be obliterated when the organs in which they are impressed have become vestigial, or races in which they existed have perished."

From the earliest stages of respiratory prodigality to the last it is the habit to encourage, coddle, coax the individual, and to sympathize with him and condone the wrong done the pulmonary apparatus, until lung inefficiency becomes more than simply endurable, but respectable, and we aid one another to gravitate toward the pulmonary zero mark.

Sentimental suppositions that prompted the lungs to conscious effort in primal times have disappeared gradually, but surely, from our traditional history, and in their stead we have the unified sentiment which gives moral support and sympathy to the pulmonary delinquent; the limit of sympathy is proportioned to the amount of the delinquency. The greater the deficiency the more profound and more universal the sympathy. While nature treats him as a culprit, we ignorantly or impiously regard him as a martyr. Tranquil pulmonary self-assurance prevails, and the fact that nature is pitiless and helps only those who help themselves is forgotten. This sentimentality is very evident in the home of the invalid, and it has long been demonstrated that home influences are too tender and unpractical for successfully combating consumption. It is a fact which needs immediate recognition and a vigorous utilization that insensate lungs should have imparted to them the touch of anarchism.

When the undoing is complete, disease is exalted to a virtue and fearlessness, or the less excusable display of hopefulness, is postulated as the worthy and noble outgrowth of the refining and sanctifying influence of prolonged physical frailty. The individual pulmonary insolvency is accredited to the victim as a species of righteousness. It is a lamentable fact, however, that the lungs die apathetically, just as their possessors elected to live. Exhausted from disuse, it is consistent that they make little ado over death. It would seem pathetic if it were not inexcusable that those of the immediate household often fail to appreciate the tragic significance of this cold-blooded expression of familiar disposition, acquisition and personal fear obsolescence.

In every possible way such misapplication of encouragement and misunderstanding of the conditions, defeat the possibilities to which science unaided can not attain. When fear is present, it is the physician's supreme opportunity to secure the delinquent's attention and enforce the measures for pulmonary regeneration. When the physician sounds the note of alarm and attempts to reawaken fear or direct its influence into the proper channels, he is regarded as lacking in the characteristics which are demanded by the present-day sentimentality. The shock, dread and fright of an intelligent appreciation of the presence of consumption is assumed to be harmful, or at least cruel, and the physician, if respectful of these feelings, is compelled to yield to the over-weening influence of friends and the subject continues his slumbrous optimism. However, there is nothing to be apprehended from well-directed fears in lung disease. Moreover, the subjects who are excessively alarmed under such circumstances, are displaying even in that alarm, less morbidity than those who display fearlessness.

#### THE EXPERIENCE OF SYRACUSE, N. Y., WITH THE COMPULSORY TUBERCULIN TEST OF ALL DAIRIES FURNISHING MILK TO THE CITY.\*

B. S. MOORE, M.D.

SYRACUSE, N. Y.

The object of this paper is not a desire to advance something new in regard to tuberculosis or tuberculin, but rather to call your attention to the great merit of tuberculin as used to-day in veterinary practice, and recite the experience of Syracuse in its use for the past four years. This experience has impressed me with its great value as a means of diagnosing bovine tuberculosis, and the hope that prompted the presentation of this paper is that such testing may soon become general and that the tubercle bacilli may be driven from the milk supply of our entire country.

I am not of those who believe that the tubercle bacillus of infected milk is the principal cause of tuberculosis in man; though not the principal. I do believe it to be a very important cause, next perhaps to the most important—that of direct infection from the infected to the susceptible uninfected. Susceptibility is as necessary and as likely in those who contract tuberculosis from the cow through an infected milk supply as in those who obtain the malady directly from a diseased man or woman. Where can susceptibility find better conditions for its full satisfaction than in the delicate baby having all the inherited weakness of its parents, feeding upon tuberculous milk and added to this a digestion too poor to destroy germ life, with the mucous membrane lining the entire alimentary canal, the seat of catarrhal inflammation, the prepared ground, as it were, ready for the seed, the tubercle germs?

The history of tuberculosis in cattle, though meager, is exceedingly interesting. At the Fourth International Veterinary Congress, held at Brussels in September, 1883, the subject of bovine tuberculosis was discussed. It was most thoroughly handled by the reporter of the Commission, Professor Lydtin of Carlsruhe, Germany. Many of the following facts and statements are taken from this report.<sup>1</sup>

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Hygiene and Sanitary Science, and approved for publication by the Executive Committee.  
1. See First Annual Report of the Bureau of Animal Industry for the year 1884, pages 350 to 366, "International Veterinary Congress, reports of Dr. James Law."

According to the law of Moses the meat of an animal that was pining away could not be used as food. More distinctly is the condemnation given in the Mishna (the collection of traditions and laws by the ancient rabbis), according to which the body of a slaughtered animal was condemned as food if the lungs could not be distended with air or had growths attached. Lydian states that this ordinance was observed by the early Christians until the third century and that diseased meat found by the overseers of markets in the city of Rome was thrown into the Tiber. The eating of diseased meat was prohibited by a law of the church in the tenth century. The sale of diseased meat was prohibited by the ancient laws of Italy, France, Spain and Germany. In 1716 a French butcher was condemned to nine years' exile, a fine of £5000 and debarred from following the same occupation, for supplying diseased meat to the army.

To France belongs the honor of having first introduced, in 1810, municipal abattoirs which are now found in most large European cities, thus rendering a thorough inspection of all slaughtered animals possible.

In the eighteenth century a strong conviction existed among the people as to the contagious character of both human and bovine tuberculosis, which is evident from the fact that consumptive persons were separated from others and after their death their clothes, etc., burned.

On Sept. 20, 1782, the King of Naples issued an edict requiring the isolation of consumptives and the disinfection of their rooms, books, etc. The punishment for violating this ordinance by an ordinary person was three years at the galleys, but a noble received three years' imprisonment and had to pay 300 ducats. If a physician neglected to report a case he was fined 300 ducats for his first offense and banished for ten years for a second.

From among professional men many can be quoted who were convinced of the contagion of bovine tuberculosis long before Robert Koch discovered the tubercle bacillus. Thus, Ruhling of Göttingen, Germany, wrote in 1774: "The malady is transmitted to sound animals by direct contact of infected animals standing side by side in the stall and licking each other, and breathing the expired air direct from the diseased lungs; the frequenting of the same pastures will also serve to propagate it." Cruzel in 1868 used these words: "This fetid expired air, inhaled immediately by another cow upon a sound lung, gives the latter tuberculous infection. It is a matter of everyday experience to the veterinarian. Two oxen or cows are kept in the same stable, take their food from a common rack or manger, lie in the same stall and respire nose to nose. The one is perfectly sound, the other is to all appearances in as good a condition, is vigorous, but it coughs from time to time, and its breath is foul. Soon it is noticed that the animal that does not cough eats with less appetite, loses flesh and soon is unequivocally affected with the same malady as the other."

With the epoch-making discovery of Robert Koch a new impetus was given to the suppression of tuberculosis in cattle. Thousands upon thousands of tuberculin tests have been made in almost all civilized countries and hundreds of postmortems have proved the almost unfailing correctness of the test.

The Empire State was the first in the Union to pass a law which conferred the power on the State Board of Health to cause an examination of milch-cows for tuberculosis or other contagious or infectious diseases.

This was during the session of 1892, Chapter 487. This was followed with Section 63, Article V, Chapter 661, of the laws of 1893, which was amended by Chapter 617 of the laws of 1894, which reads: "It is the duty of the State Board of Health to investigate concerning the existence and cause of tuberculosis in cattle and use all reasonable means for averting and suppressing such disease."

In the report of the commissioners on tuberculosis in cattle in the state of New York, which was transmitted to the legislature on Jan. 24, 1895, we find on page 8 a "summary of all cattle examined, condemned and slaughtered by the Tuberculosis Commission, with the distinctive breeds," according to which up to the year 1895, 2417 cattle had been submitted to the tuberculin test, of which number 405, 16.75 per cent., or one-sixth, were found to be diseased and were condemned and slaughtered. During the year 1895, there were tested in Onondaga county four herds of cattle. Again, in 1898 the Committee had tested 17 herds of cattle for the Syracuse Milk Supply, and the Committee says: "Where no disease was apparent by physical inspection 4 per cent. were found diseased."

The 15th Annual Report, for 1898, contains the report of Health Officer Dr. O. A. Thomas, in which he calls special attention to the resolution introduced by him to the Board, and passed at the December meeting, compelling all persons peddling, selling or delivering milk in Syracuse to have on or before April 1, 1899, a certificate from a competent veterinary surgeon, that their cows are free from diseases.

The 16th Annual Report, for 1899, contains the results of the first general compulsory testing of the cows supplying the city of Syracuse with milk, and it is as follows: No. cattle submitted to the tuberculin test, 3843; No. cattle responding to the test, 200, or about 5.25 per cent. This testing, with the condemnation of 200 cows from the herds supplying milk to the city met with some opposition and an outspoken determination that it must not be repeated.

At the beginning of the year 1900 all dairymen were notified that their herds must be tested and must be retested every second year; that new cows added to the herds would be tested the intervening year. The dairymen held meetings, expressing themselves freely pro and con in regard to the test. All licenses had expired on April 1, and on April 25 the milk producers in convention had decided not to allow their herds to be tested by tuberculin. They, at this time, appointed a committee to obtain the best legal advice upon the subject, and found that they must conform to the requirements of the Health Bureau or keep their milk out of the city; which they determined to do until such time as they could bring the Health Bureau to change its position. The Health Bureau then gave notice that any person selling milk without the proper license on or after May 1 would be arrested. From this time until May 1, every peddler presented to his several patrons a petition requesting them to sign against the test. This measure was a failure, few signatures were obtained and the petition never appeared.

May 1 dawned bright and warm, but the familiar rattle of the milk wagon was not heard on the streets. These conditions lasted three days, during this time public sentiment and expression of our local press remained entirely with the Health Bureau. No complaint ever reached us, though doubtless many suffered at the stopping of so necessary an article of food. At noon on

the third day the dairymen desired a compromise, but we had none to make. A clergyman waited upon us and thought that as the tubercle bacillus might exist in butter and cheese, it was foolish to endeavor to exclude it from the one article—milk. I said: "Though you are not able to stop all the vice in the city, you do endeavor to stop some by preaching to your congregation every Sunday." An hour after, the Onondaga Milk Association, the largest milk producers in the city, requested and obtained an extension of ten days' time in which to have their cows tested. Their example was quickly followed by all other dairymen and our milk war was over. Very material support was given the Health Bureau by our Commissioner of Public Safety, Mr. Duncan W. Peck, and by the Syracuse Academy of Medicine, especial gratitude being due Drs. H. D. Didama, John L. Hefron and Frederick W. Smith, formerly of the State Board of Health.

This year's testing has been carried on with the kindest feeling existing between dairymen and the Health Bureau. Many dairymen who have investigated the subject have the greatest faith to-day in the test and will oppose it no more.

It is but fair to say that the majority of farmers were honest in their opposition and have since shown a desire to investigate the worth of tuberculin. I will repeat the history of one such case: Mr. A., an intelligent gentleman, the owner of a fine milk farm, had a cow that reacted to the test with a typical temperature that remained at 104 or above. She was condemned, the attending veterinary telling Mr. A. that he would give him a \$20 gold-piece if she proved non-tubercular. The dairyman regarded the cow as one of his best animals; she was giving an extra large amount of milk, was sleek, fat, and appeared a cow in perfect health; but he desired to know the truth and only agreed to sell her when the butcher promised that Mr. A. should be present at the killing. I was notified at 2 p. m. that this event was to take place at 3 p. m., and after telephoning to several physicians, drove rapidly to the place of slaughter, where I found the cow nearly dressed and the butcher working hard in his endeavor to have the job all over and all evidence of tuberculosis removed before the time appointed for the killing and the coming of the veterinary. Mr. A. and his son, both at that time unknown to me, were careful spectators of the proceedings; the butcher repeatedly assuring them as he worked that "there wasn't a pimple on her." The lungs were still to be removed, and their removal I carefully watched. The butcher hung them up as quickly as possible after removal, so a decided enlargement by the apex of one lung was turned in and covered. I asked that they remain there for a short time, until the veterinary should arrive, and as I saw a carriage approaching I stepped toward the front of the building. The butcher was watching and when he saw me speaking to a physician who was just entering, he made a quick sweep of his knife and the enlargement dropped from the lung. He was not quick enough. I returned and picked up the piece, which was an enlarged bronchial gland, weighing one and one-half pounds, a beautiful specimen of solid tubercle in the cheesy degenerative state, the center of the mass soft and ready to break down. The specimen was preserved in the Syracuse Medical College, after the city's bacteriologist had found bacilli in large numbers. Mr. A. from that time has remained a friend of the test. He was much surprised

by the findings, remarking that this cow had never shown any visible signs of disease.

No. cattle then submitted to the tuberculin test, 1127; No. cattle responding to the test, 52, or about 1.26 per cent.

No. cattle submitted to the tuberculin test this year, 731; No. cattle responding to the test, 2, or about 0.27 per cent.

You will notice the gratifying decrease in the percentage of reacting cows: Five and one-quarter in 1899; one and one-quarter in 1900, and one-quarter in 1901.

The following facts give us some idea in regard to the prevalence of bovine tuberculosis: During the year 1889 there were killed in eleven abattoirs of the Kingdom of Saxony, in Germany, 56,723 cattle; of these 8 per cent. were affected with tuberculosis, namely, 12 per cent. of cows and 5 per cent. of heifers. Dr. Reick gave a careful report of the Leipzig abattoirs for the three consecutive years beginning with 1888. During this time 68,000 beeves were slaughtered, and of this number, 14,000, or about 20 per cent., were tuberculous. We should expect these animals to be in health conditions above the ordinary dairy cow. The London *Lancet* of April 15, 1899, gives an account of the testing of the late Queen's herd of 40 cows on her farm at Windsor; 34 head were condemned. The Queen ordered the whole herd slaughtered, requiring postmortems in every case by the Royal College of Veterinary Surgeons. These examinations proved the reliability of the test. Many such instances can be cited, such as the case of the fine herds of the late Governor Morton of New York; but perhaps the one that was most convincing to Syracuse and vicinity, was that of the herd of De Wayne Brown of North Pharsalia, N. Y. These animals had been submitted to the tuberculin test on June 14, 1899, and condemned by the State Board of Health. With the desire to convince the doubting milk-producers of Syracuse of tuberculin's value, they were brought to Syracuse and slaughtered. The results of the autopsies made under the direction of Prof. James Law, of Cornell University, proved that every cow of the herd of 21 was more or less diseased.

Milk, an indispensable article of food, universally used, must be separated from any suspicion of infection from a bacillus the cause of the most common and at the same time the most fatal of diseases. That such infection exists to-day is admitted on all sides by scientific men who have investigated the subject. There is a difference of opinion as to the extent of the danger, slight perhaps in the milk of animals having small encysted tubercular deposits, greater as the disease becomes general or when the udder is affected; so to-day the consensus of opinion from medical men is that a cow no matter how slightly tuberculous, should not produce milk for human consumption. The danger of infection admitted, is it possible to crush out bovine tuberculosis from the herds of our country? With no hesitation, I answer, yes. What any careful farmer can do for his herd, and what very many such farmers have done for their herds the state can do for all herds within its confines and the same care can be exercised by the state in admitting cattle within its limits as is exercised by the careful farmer in admitting new cows to his herd.

This, the first year of a new century, should be marked by a determination in medical men and medical societies

to block every avenue of attack of the tubercle bacillus, to-day the recognized cause of "the great white plague." We are not compelled to work in the dark as were the physicians of past ages. We know exactly the cause; we know exactly the favoring conditions for the multiplying of that cause; the chief means for the growth and spread of the tubercle bacillus can be counted on the fingers of one hand; and it is to us that the laity look to check this dread malady, and for the knowledge that they may intelligently protect themselves against infection and even in the majority of cases save their lives after infection. If this year and this new 20th century could be recognized and adopted by physicians the world over for united effort against one and all means of travel and development of the tubercular germ, what a grand result this effort would show at the century's close, and at the birth of the next, the 21st century! Tuberculosis compared with now would be a rare disease, and medical men would well be repaid for 100 years of hard united work.

# CLIMATOGRAPHY OF ARIZONA, WITH ESPECIAL REFERENCE TO THE CLIMATIC TREATMENT OF PULMONARY TUBERCULOSIS.\*

ROBERT W. CRAIG, M.D.

PHOENIX, ARIZ.

Of all diseases which have wrought devastation to the human race, there has never been a disease more deadly or more widely distributed than tuberculosis. Other communicable diseases have caused more dismay, and occasionally, for a short period, even greater destruction; but tuberculosis has been, and to a lesser degree continues to be, the most constant and virulent of all. It has been recently estimated that there are one million cases of active tuberculosis in the United States, and the latest authentic statistics show that 14 per cent. of the deaths recorded for ten years are due to some form of it.

Climate, as affected by mere latitude, does not seem to have any influence on the disease. The death-rate from this cause is practically the same in New York, at a latitude of 44 degrees, and Manila, which is only 15 degrees from the equator. On the other hand, a low relative humidity seems to be a very potent factor, and in the Alps, the Rocky mountains and the great interior plateau of South Africa the disease is very rare.

In all localities where there is a relative immunity from the disease, the climatic conditions are such as to allow or compel their inhabitants to live largely an outdoor life. Knopf says: "Were I to be asked to express an opinion on the subject, I would say the best climate for the tubercular patient is the one which permits him to remain outdoors more and longer at a time than anywhere else." In other words, that place having the most sunshine, least moisture, and most even temperature is the ideal spot. Believing that Arizona very nearly fulfils these conditions, and is probably less known to the profession than most other sections of the country, its climatic conditions have been made the basis of this article. Variations in climate are wholly due to variations in the physical conditions extant. These are generally local in character and few in number. The atmosphere at a short distance above

the earth's surface is practically the same everywhere, but at the surface it varies somewhat. The most important of these variations are, 1, temperature; 2, air-weight as determined by altitude; 3, humidity; 4, sunshine. As these physical conditions vary with the parts of the earth's surface, it may be said there are no two climates exactly alike, and it is practically impossible that there should be. The most potent factors in determining these variations of climate are latitude, altitude, and large bodies of water.

1. Studying the climatic conditions of Arizona on this basis, we find that they are certainly unlike anything else in the world. The Territory is located between the two greatest ranges of the Rocky mountains, between 30 and 35 degrees North latitude. It is largely comprised in an extensive plateau that has climatic features so distinctive as to merit a separate place in the classification of climates. Hundreds of miles from any large body of water, traversed by lofty mountain chains, and surrounded for several hundred miles on every side by sandy deserts, it has the natural physical conditions which combine to make it the ideal climate for the consumptive. We rarely contemplate the far South latitude of the region when thinking of Arizona, but nevertheless it is almost exactly of the same latitude as Cairo, in Egypt, and the greater portion of the Territory has a very similar climate.

The general slope of the country is toward the south and west, ranging from an average altitude of 7000 feet at the Grand Canyon and around Flagstaff, in the northern part, to sea level in the south and west, in the locality of Yuma, which is erroneously but popularly supposed to be the hottest town in the United States. The northern and eastern portions of the Territory are to a very large extent mountainous, and covered with pine and cedar forests, which, being almost entirely clear of underbrush, form magnificent natural parks. This region is the watershed from which source is derived the water used for irrigation of the famous Salt River valley, which bears to Arizona the same relation as does the valley of the Nile to Egypt, and which archeological authorities claim has been under cultivation for an even longer period than that valley.

The two principal towns in the northern part are Flagstaff and Prescott. Flagstaff is a beautiful little city of 2000 inhabitants, and was certainly intended by nature for a summer resort. It has an altitude of about 7000 feet, and is located about the center of the National Forest Reserve, which includes the San Francisco mountains and the Grand Canyon of the Colorado. During the warmest summer months the temperature here rarely exceeds 80 degrees, and at all times blankets are necessary to comfortable sleeping. This region is particularly rich in the natural objects of interest which are so necessary to occupy the time and attention of the semi-invalid. The Grand Canyon of the Colorado, certainly the greatest scenic wonder of the world, is now reached by railroad, connecting with the main line of the Santa Fé at Williams, as well as by an automobile line which makes the trip from Flagstaff to the rim of the Canyon in eight hours. In and around this region within driving distance of Flagstaff are Montezuma's castle, probably the most famous of the Aztec ruins, Montezuma's well, the crater of an extinct volcano, a petrified forest, Cataract Canyon, with its village of Supai Indians, and beautiful waterfalls, and Walnut Creek Canyon, with its cave and cliff dwellings. The mountains and canyons in this locality are the

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Hygiene and Sanitary Science, and approved for publication by the Executive Committee.

sportsman's paradise. In the southern portion of the Territory is the Salt River valley, which is probably the objective point of more people seeking to escape the rigors of the northern winters than any point in the Southwest. This valley is about 60 miles long by 30 miles wide, and is as level as a floor, with a gradual slope to the southwest. It was at one time the seat of Aztec civilization, and it has been estimated from the immense ruins found in various parts of it that this region formerly had a population of about 300,000. Even now, ancient canals may be distinctly traced, demonstrating that a most elaborate and extensive system of irrigation was carried on. Near Phoenix, Casa Grande and Temple, are the ruins of prehistoric cities that were beyond question more populous than any now in existence between Denver and the Pacific coast. This valley is now largely under a high state of cultivation and is a veritable oasis in the desert. It is mostly given up to citrus fruit growing, and the orange groves within five or six miles of Phoenix are one of its most attractive features. A belt stretching for miles along the foothills produces the finest oranges grown in America, and a ride along some of the driveways skirting the canals which supply the water for irrigating these fruit orchards is one of the best tonics available. Killing frosts are practically unknown, and even during January and February, the coldest season here, the apricot and almond trees are in bloom and alfalfa fields are as green as an Illinois lawn in June.

Phoenix, the capital and commercial center of the Territory, is located in the Salt River valley and is a thoroughly modern town of about 15,000, with electric lights, street cars, the best of winter hotels and probably more churches and schoolhouses than are to be found in towns of equal population in the East.

As the manifold climatic advantages of this Territory, chief of which are an even temperature, medium altitude, minimum humidity and maximum amount of sunshine, are becoming more and more clearly recognized by the medical profession in the East and North, the tide of winter travel is tending in this direction, until Phoenix, in particular, of its many towns, is the objective point of a far greater number of pulmonary cases than any other city of equal population in the Southwest. The greatest number of invalids are of the tuberculous class.

They recover in encouraging numbers; in such proportions, indeed, that it is the strongest argument that suitable cases should invariably be sent from the colder regions of the North and East to a climate where the conditions are such as to make an outdoor life the natural existence. By passing the summer in Flagstaff, the fall in Prescott, the winter and spring in Phoenix, the invalid may enjoy the advantages of the Riviera and the resorts of Switzerland and Egypt with practically none of their disadvantages.

In a consideration of the individual factors controlling the climatic conditions here, temperature and a low relative humidity may well be considered the most important, as the even high annual temperature and dryness of the atmosphere are Arizona's chief claims to merit, as compared with many other good climates.

1. The temperature of Arizona is higher than in some regions of the Mississippi valley, by an average of fifteen to twenty degrees in summer, and by thirty to forty degrees in winter. Yet the relative humidity is so low in summer that the sensible temperature is five

to ten degrees lower in Arizona; that is, the sensibility of the human body to heat is really less in Arizona than in Illinois. A temperature of 110 degrees in Arizona is much less unpleasant than a temperature of 90 degrees in Chicago. Thermic fever is unknown, even in the hottest summer months. I have known of a few persons somewhat overcome by the heat, but they never had elevation of temperature, or the symptoms common to sunstroke, and a careful inquiry generally elicited a history of alcoholism. The government reports show an average temperature for fourteen years at Phoenix for December of 65 degrees, for January of 58 degrees, and February of 63 degrees. The nights throughout the winter are apt to be cool enough for open wood fires, and for blankets. Generally overcoats are not needed during the day, even in the midst of winter.

2. The variations in altitude are very pronounced, and this is a striking advantage in some respects, as with the same general conditions as to temperature and dryness of air the physician is able to select nearly any altitude he may desire, ranging from sea level at Yuma to 6800 feet at Flagstaff. The improvement in nutrition, particularly the great increase of red blood corpuscles that sometimes occurs upon removal to a higher altitude is remarkable, but I believe the intense expansion of the lungs in these cases is detrimental rather than otherwise. That an enlargement of the thorax follows a residence at a high altitude there is no question, but the increased resonance of the percussion note is, I believe, generally due to an emphysema produced by the altitude rather than to increased lung power. The theory advanced by Murphy in support of the nitrogen gas treatment, that the diseased lung needs rest rather than unusual activity, is entirely logical, and I believe that, as a rule, the good results secured by sending patients to high altitudes are due primarily to other causes, notably dry air and improved hygienic surroundings, rather than to the effect of the high altitude.

3. A low percentage of humidity is, I believe, the most important essential in the elements that go to make up the ideal climate for the treatment of pulmonary tuberculosis. Other conditions being equal, tuberculous cases improve much more rapidly, and a greater percentage of recoveries is found where the relative humidity is lowest.

The lack of moisture in the atmosphere, as reported by the United States Weather Bureau, at Phoenix, is truly surprising. On several occasions during the month of June, 1900, the relative humidity fell as low as 1 per cent., as compared with 50 and 60 per cent. in Chicago, and eastern cities.

The average annual rainfall recorded at Phoenix is 6 inches, as compared with 35 inches at Asheville, N. C., 18 inches at Los Angeles, and 15 inches at Denver, Colo. The official weather reports demonstrate that Phoenix has the lowest percentage of humidity and the maximum amount of sunshine of any city in the arid belt, which effectually controverts the statement that has been made that the irrigation in the Salt River valley had interfered sadly with its climate for pulmonary cases.

One especially noticeable effect of the dry air is the great diminution in the amount of sputum in those cases where there is excessive bronchial catarrh accompanying the tubercular lesion.

4. The value of a maximum of sunshine can hardly be overestimated, as the relative humidity and the

temperature depend to such a large extent upon it. Its mission can not be fulfilled by the model comfortable house, and, as the love of sunshine is proverbial, its influence in inducing patients to live outdoors is perhaps greater than any one other climatic feature.

Knopf, in his excellent work, speaks of the great amount of sunshine enjoyed by invalids at Davosplatz, Switzerland, mentioning that the average daily sunshine for the month of November is 4 hours, 16 minutes, which is truly a relatively large percentage; but when compared with the 9 hours, 12 minutes reported by the United States Weather Bureau at Phoenix, for the same month is small indeed.

Phoenix has the greatest percentage of sunshine recorded by any United States Weather Bureau office, and during the year 1900 there were but five days on which the sun did not shine there. This is a matter of the utmost importance, as the entire trend of modern ideas upon the subject is toward the outdoor treatment, and my experience has been that it is extremely difficult to induce patients to remain in the open air when the weather is cloudy or bad.

The mental condition of the average tuberculous subject corresponds very closely to the barometer. When the day is cloudy and the humidity is great, he is depressed and melancholy. When the sun is bright, his spirits rise, and he wishes to be outdoors as long as possible, and does not suffer so severely from nostalgia, which has such disastrous results in many cases.

In discussing the various forms of tubercular lesions, particularly those involving the pulmonary tract, it must be borne in mind that in many cases there is a spontaneous healing which has been demonstrated by postmortem and pathologic investigations. The very fact that these spontaneous cures do occur, and the evidence is abundant, frequently in cases where a tuberculosis has never been even suspected, is sufficient evidence that conditions may arise or be induced within the patient suffering from tuberculosis which will check the course of, and in many cases entirely eliminate, the disease.

In all tubercles two processes go on—the one, caseation, destructive and dangerous; the other sclerosis, conservative and healing; the ultimate result depends, in the given case, upon the capabilities of the body to restrict and limit the growth of the bacilli. To produce and strengthen these capabilities must be the aim of all curative treatment, whether it be by specific medication or by the open-air treatment. (Osler.)

Regarding specific treatment, the various new cures so frequently presented to the profession, and through it to the public, are the best evidence of our lamentable weakness in that direction. As yet there have been no indisputable evidences of benefit derived from the treatment of pulmonary tuberculosis by the serums or tuberculin, and my personal observation leads me to believe that there have been many more tuberculous patients hurried to an early grave by the use of creosote, guaiacol, ichthyol, etc., than have ever been benefited by them. Many of our best writers condemn tuberculin in no uncertain terms, and I feel sure that not many of us, if suffering from tuberculosis, would use it individually, except, perhaps, for diagnostic purposes. Karl von Ruck clearly demonstrated the worthlessness of the serums.

To my mind, the most important of all is the open-air treatment. The principle which this plan of treatment recognizes as of vital importance, without which

all else is naught, is comprised in the three essentials to perfect animal life, namely, pure air in unlimited quantities both day and night, good food and plenty of it, and, as near as possible, complete repose. The benefits to be derived from this mode of treatment are coming to be widely recognized, and statistics of such open-air institutions as Nordrach, in the Black Forest; Kimberly, in South Africa, and Falkenstein, near Frankfort, all testify to its efficacy. The method pursued by the more modern sanitariums, particularly those above mentioned, is to give the tuberculous patient, as nearly as possible, an absolutely outdoor existence. Undoubtedly the best results attained here have been by a tent life on the desert at the foothills, which extend within six miles of Phoenix. Indeed, many people sleep practically in the open air all winter, although it is not so commonly practiced as it should be when carried out under intelligent direction. In brief, we may summarize as follows: Pure and abundant air both day and night, indoors and out; such good and plentiful food as a simple, open-air life may enable a patient to digest; rest, frequent and complete; a long night of sleep; an hour's rest after walking, additional rest when the individual may require it; and in all cases absolute avoidance of fatigue.

#### DISCUSSION IN SYMPOSIUM ON TUBERCULOSIS.<sup>1</sup>

A MEMBER—I ask Dr. Salmon how much danger he apprehends from the beef of animals that were tuberculous?

DR. D. E. SALMON, Washington, D. C.—I purposely avoided that question in my paper because it is so much contested at this time. I spoke somewhat of the danger of tubercular material existing in the muscular tissues of animals, a condition which is illustrated by some of the specimens which I have put in the pathologic exhibit. It is generally admitted, I believe, that there is not very much danger from meat. Whether that is a correct conclusion or not, I am not prepared to say. The English investigations made by the Royal Commission showed that when tubercular matter was included inside of the roasts of beef, with ordinary cooking, it was not destroyed. They also showed that the butchers in dressing the carcass would cut through tuberculous glands and other structures, and carry the infectious tubercles on their knives to the muscular tissues; and they appeared to think that there was considerable danger. On the other hand, the postmortems on adults showed that the lesions of tuberculosis starting in the abdominal region do not appear to justify the conclusion that there is a very large number of cases occurring from meat; that is to say, there appears to be a very comparatively small proportion of tuberculosis in adults that start in the abdominal region.

There is a good deal to learn about that yet, and for that reason I rather laid stress on the danger from milk, which none of the authorities who have looked into the matter carefully have contested. It is generally admitted that there is a good deal of danger from milk. Certainly there is more than there is in meat. We want to establish the point first that there is danger from milk, and for that reason we are putting our work upon that. After that is done, perhaps attention will be turned more particularly to meat; but for the time being it is admitted by all that the danger is principally from milk.

A MEMBER—In Germany, do they not allow all meat of tuberculous animals to be sold?

DR. SALMON—The carcasses which show generalized tuberculosis—that is to say, which show that the bacilli have been distributed to the carcass by the blood—are condemned. But there is a chance for a difference of opinion as to what is a generalized case and what is not. We would call sometimes a case one of generalized tuberculosis that others would not, and so that makes some difference. That class of cases amount

1. For the papers of Drs. Salmon and Robison, see *THE JOURNAL* of December 28, and for the papers of Drs. Bracken and Ambler, *THE JOURNAL* of January 18.

from 2 to 3 per cent. that are condemned and destroyed. Then they have another class of cases, where there is extensive tuberculosis, that they sterilize, and then they allow it to be put on the market. This is sold as inferior meat. That constitutes probably 5 or 6 per cent. of the tuberculous carcasses, making, with the generalized carcasses and the sterilized carcasses, from 7 to 8 per cent. that are either destroyed or sterilized. The balance of the cases of tuberculosis are put on the market without restriction.

DR. M. H. REYNOLDS, St. Anthony Park, Minn.—The prevalence of bovine tuberculosis in our country without regard to breed is admitted, and all breeds are affected. A large percentage of all these cases are mild and latent. The cattle are sleek and fat and look the pictures of health, and it is difficult to convince people that they have tuberculosis, or anything except perfect health. Another difficulty that veterinary sanitarians meet is the indifference of the general public, of stock owners, and particularly of breeders of pure-bred cattle. There lies the most difficult problem of all: tuberculosis in pure-bred herds. For breeders to stand any chance in the show ring, their cattle must be excessively fat. That means that the animal has been idle for a long period of time and has been kept under artificial conditions. It is true that many herds of pure-bred cattle are kept under very artificial conditions, and it is also true that there is a great deal of tuberculosis among such cattle. Then again comes in the complication that they are so very valuable. We can kill and pay for cattle worth \$40 apiece, but we can not condemn or kill or quarantine for any long period of time cattle worth from \$300 to \$1200. We can never get our legislature to appropriate enough money to pay for very many pure-bred cattle.

Dr. Salmon mentioned the point that there was a present tendency among medical men to belittle the danger to human life in the use of tubercular meat and milk. That danger may have been overestimated, but we are now at the danger point of going to the other extreme and belittling a serious problem. We should not do that. Sweeping, general measures are hopelessly impracticable. Measures that would attempt to test all cattle in this state and destroy all carcasses of reacting cattle, or even permit the sale of a portion of the carcasses, are impracticable. It being granted that we can not go through the state and test all the cattle within her borders, the question arises: What then can we do? First of all, we can get the people of the state, particularly the heads of families interested in knowing what sort of herds the milk comes from that their children are using, and here is a good work that medical men can help along a great deal. I am afraid that there are a great many medical men in our cities that never think of suggesting to their families the desirability of knowing what sort of dairies the milk comes from. Physicians in private practice can do a grand work by getting their people interested in this subject. So far as I know, Minneapolis was the first city that really undertook serious work along this line. In 1896 work began in Minneapolis on the plan of not ordering that all cattle should be tested, but merely saying by ordinance that unless herds were tested owners could not sell milk within the city limits. Dr. Moore told us of their experience in Syracuse. We went through a similar experience in Minneapolis. The measure was fought bitterly by the dairymen's association, and the first year it was slow, up-hill work. The second year was a little better, but gradually the measure gained support among the dairymen themselves, and within the last year expressions have been very free among dairymen of the Twin Cities, and particularly Minneapolis, that they believed it was a good thing. That they believed there was such a thing as tuberculosis among their cattle, and it was a good thing to have their herds tested; that the people should have milk free from non-tuberculous cows, etc.; but at the same time they would say they didn't think it was just that dairymen should stand all the loss of the condemned carcass. Last winter the legislature made provision for paying a part of this loss, so that now the cattle owner gets two thirds of an appraised live-stock value.

I do not see any way at present where we can accomplish much except by affecting the owner along the line of his pocketbook. If we can show him that it means dollars and

cents to him now, or at some time in the future, we can accomplish a great deal. Owners are very loath to have their herds tested with the possibility staring them in the face that large portions of their herds may be tuberculous, and I am afraid that many of us would look at the thing as they do if we were in their place. If we can get a few breeders to advertise that their herds are free from tuberculosis, and that every animal has been subjected to the test, or if any arrangements can be made to advertise their herds and make their stock more valuable, I think we can accomplish a great deal along that line.

The difficulty has always been, and always will be, with cattle of that class, the artificial conditions under which many of them are kept. It is one of nature's laws that an organ or a tissue that is not used, or used less than nature intended that it should be, must necessarily lose in nutrition and vitality and become subject to disease, and so, when cattle have been kept fattened and standing for months, although they may be fat and nice looking, they may also at the same time be tuberculous, and will be very apt to be so. One thing that we can accomplish along that line is to induce the breeders to give their cattle better hygienic conditions, more sunshine, more air, and fewer dark stables.

DR. NORMAN BRIDGE, Los Angeles.—It seems that, admitting all the difficulties of accomplishing good we all hope and wish for, there are a few directions in which our efforts should be exerted because they are practical. We should encourage dairymen to have their cows free from tuberculosis by limiting their sale of milk; that always brings them to the point. It can be done in any city as well as it has been done in Syracuse. It only requires courage. The people are willing to pay enough more for the milk to reimburse the dairymen for losses. From an economical standpoint that point must be conceded. If the dairyman is obliged to lose some of his cows he must be reimbursed in some way, and it means paying more for milk by the citizens who consume it. That I believe the citizens would always be willing to bear, and all that is necessary is for the boards of health and the governing bodies of cities to insist on these measures. They not only do a great deal of good in the ways that have been mentioned, but they are educative to the public. I should have been glad if Dr. Moore had told us somewhat more of the inspection of the dairies of Syracuse; whether the inspection extends to other conditions than tuberculosis. It seems to me that we ought to encourage the health departments of cities not only to inspect herds for tuberculosis, but as to their general cleanliness, and the hygienic conditions of the stables, and the utensils used, as well as that the milk shall be free from contamination and shall not be adulterated or lower in standard. I sanction everything that has been said in favor of the inspection of dairies as to tuberculosis. That is one practical thing that we can do to prevent the spread of this disease. Another practical thing is the erection of sanatoria. The people are becoming educated to the seriousness of tuberculosis and its communicability, and in no new or novel direction can they be helped so much as in the direction of an increase of sanatoria. The great majority of the people can not go to sanatoria that require them to pay for their board. There ought to be free sanatoria for indigent patients, at the public expense, and we ought to agitate for such to be erected and conducted by the state. All reforms are brought about in this way. We must insist on great things, and then we will accomplish some small things. All people with tuberculosis ought to be in sanatoria, unless they can take perfect care of themselves at home.

DR. H. M. BRACKEN, Minneapolis—I notice on the program the word "sanitaria." I would be sorry to see this word come into general use. Many quack institutions about the country have been known as sanitariums. The places where we send tuberculous patients are not sanatoria; they are sanatoria, and I do hope that this Association will be particular in its choice of these words. There are two or three good institutions in the United States where tuberculous patients are treated, that are known under the name of sanitarium, but it is not the general term, and not the correct term, and I think it will be well for us to be careful to observe the correct term.

I am strongly in favor of the tuberculin test, and I think it is well to have the dairymen working with us in its use. They are taking an interest in the matter in St. Paul and Minneapolis, and I hope it will become a matter of general interest in this state. But we are not going to secure a non-tuberculous milk supply simply by testing cows for tuberculosis. Take, for instance, St. Paul and Minneapolis. The testing is done by the sanitary authorities of the city. A herd is tested to-day, we will say, and a number of cows are condemned, and go to the slaughter house in a few days. The owner has his regular customers and he must keep up his milk supply, he therefore buys other cows to replace those that have been killed. He has no evidence whatever that the cows he has just bought are any better, or as good even as those which have just been killed. But the cows that he has bought to take the place of those just killed will not be tested for tuberculosis for possibly ten months, possibly two years. It is impossible for the authorities of the city to get around to these various herds at very frequent intervals.

The dairy barn should be looked after closely, and should always be disinfected after infected animals have been taken from it. I heard a dairyman, recently, speaking of a neighbor who had a number of cows that had been condemned and killed, say: "That man will be just as bad off in a short time as he is now. His barns are not fit to keep animals in. There is only one way for him to save his place, and that is to set fire to his sheds. They can not be disinfected in any other way without great expense."

DR. A. S. MOORE, in reply—When a veterinarian at Syracuse makes an affidavit that he has tested the cows for tuberculosis we also require an affidavit from him that those stables are all in a sanitary condition. We have inspectors who visit these stables frequently, and anything that they regard as unsanitary is reported to the Health Bureau. We believe that we have a good man in the person of Dr. Engelhardt, of our city, who has been connected with the department for many years, and who is a first-class chemist and understands all the phases of bacteriology and the means of destroying disease-producing germs and their spores. He gives instructions as to what must be done in order to make the stables clean and sanitary and the course to follow to keep them so, in the way of acquiring better light, sunshine, etc. When necessary, he condemns a stable; then a notice is sent into the health department of his action. A certain time is given to the owner of the premises to make it right, and if he refuses to do so we simply ask him to keep his milk out of the city until such time as he makes up his mind to remedy the evil.

THE CHAIRMAN—May I ask you, Doctor, what jurisdiction you have beyond the city confines?

DR. MOORE—We have no jurisdiction. All we can do is this: If he refuses to do what we ask him, then we tell him to keep his milk out until he does do it. We have inspectors working all the time. They have nearly three hundred herds to examine; they probably get around every three or four months to each herd. We find in our vicinity that the dairymen in buying cows often make it a provision in their contracts that the cows shall be submitted to and stand the tuberculin test, or they refuse to make the purchase.

DR. REYNOLDS—I would like to ask Dr. Moore if in the beginning of his work in Syracuse he met with opposition on the ground that the tuberculin was injurious to the non-tuberculous cattle, because of a great number of abortions, etc.

DR. MOORE—We met with a great deal of opposition, and a great many farmers seemed to have data that warranted this opposition, but after investigating the subject I believe to-day that there is no such opposition on that ground. I remember that one man claimed that a part of his cows had aborted, and we asked one of our local veterinarians to go and find what was the cause of so many abortions among the cows of this dairy; he came back and reported to us that he believed it was due to the fact that the farmer fed his cows a large amount of salt, mixing it in their feed in too great a quantity. This man had been feeding his cows that way, and that this trouble was not in any way connected with the tuberculin test.

DR. D. E. SALMON, Washington, D. C.—The first thing I did was to test animals coming into the United States from other countries, and we found from 20 to 40 per cent. of pure-bred cattle coming in that were tuberculous, and we made a regulation that they should be tested in our quarantine stations, but we found there were so many that had tuberculosis that it was entirely too large a problem for us to attempt to slaughter those valuable cattle, so we put a man in Great Britain to test them before they left there.

Now, I have met in some quarters with the most intense opposition in doing anything, even excluding tuberculous cattle, and one reason of my coming here and presenting this paper was to get the interest and support of the medical profession. I believe that those engaged in this work need that support. They need the influence of the members of the medical profession, for it has such great weight in the country; not only because they are intelligent men, but because they are supposed by the people in the country to know about such questions, and it will go further than anything else to strengthen our hands in regard to the measures which should be adopted and enforced.

I have been thinking that when the time gets ripe for it, and it may be before long, there should be provisions made for preventing tuberculous animals going from one state to another, but we will be obliged to do a great deal of educational work before we can undertake that, and it is with the hope of doing that educational work largely through the medical profession that I came to this Section with the paper I have presented. It has been reported to us over and over again that you can go and slaughter dairy cattle every year if you please and yet the next time that you inspect the dairy herds you will find as much tuberculosis as you did in the first place. Dr. Moore has shown that the first year he had about 5 per cent., and the next year it was reduced to 1.25 per cent., and in three years it was reduced from 5.25 per cent. to one quarter of one per cent., which it seems to me is a most remarkable showing, and if half as good work as that can be done generally throughout the country by boards of health, it certainly would have an immense influence for good.

## BLOOD EXAMINATION, FROM THE STAND-POINT OF THE GENERAL PRACTITIONER.

F. W. HIGGINS, M.D.

CORTLAND, N. Y.

The relation of the laboratory to the practice of medicine is a topic which has been abundantly discussed in the recent journals. In our modern hospitals the clinical laboratory is considered indispensable; here, urine analysis, blood counts, serum reactions and bacteriological diagnosis are daily occurrences. Our journals are filled with reports of microscopic investigation; many of these articles are "preliminary" and our memory may leave us doubtful whether further examination has confirmed or denied these bids for precedence.

One of the most enticing of these laboratory studies is the examination of the blood. The beautiful proven results furnished the profession from time to time, and, still more, the brilliant promises of what may be expected in the future make the subject of absorbing interest to the scientific physician of to-day. This holds true, whatever his specialty may be. Many lesions of the eye are found to be explainable only by an examination of the blood—the retinal hemorrhages of leukemia, for example. The surgeon finds the number of leucocytes and the percentage of hemoglobin very important factors in diagnosis and prognosis. The specialist in skin diseases counts the eosinophiles. In internal medicine it may be said that the diagnosis of no case is complete until an examination of the blood has been made.

If now we expect that in a modern hospital the examination of the blood should become a routine like urin-

alysis, and that important aid in diagnosis, prognosis and treatment will thus be obtained, is it possible for us as general practitioners to gain some benefit from undertaking such examinations? This is the problem which the writer of this paper has stated for himself. His object is to determine how much of all the mass of published observations on the physical, chemical and microscopic examination of the blood may be utilized by us in general practice.

First, in considering this question we must recognize our limitations and rule out all hope of making original investigations. It is true that Koch discovered the bacillus tuberculosis while a general practitioner. Nor do I forget that this is a new and promising field for exploration. Few, however, have the ability requisite for solving the many existing problems in the study of the blood. Our humbler mission is that of sifting the proven results from those not yet substantiated and adapting them to our every-day requirements.

Another limitation that must be recognized is the time element. The hackneyed "busy practitioner" has several spare half-hours, if he will husband them, that might be utilized in the clinical examination of the blood of his patients. But it is manifestly impossible for him to give to the task more than fragments of time. Therefore, he must choose the less complicated methods. It is necessary that he have a table especially devoted to such work; that he have a north light, and that his microscope always stand ready before the window; that his stains and instruments are all ready labeled and at his elbow; that he have some one to clean up the apparatus after him and put all back in the proper place; that he have the steps of each examination tabulated and in front of him; that he keep everything scrupulously clean; and, lastly, that he does not undertake too much. Another precaution which Janeway tells us is not unnecessary even in larger laboratories, is to label each specimen and step, immediately, that the final conclusion may be applied to the right patient.

The financial side of the question is one which will occur to most of us, even when smitten by the scientific possibilities of such study. Something may be done with such an outfit as every physician should possess. A microscope with 1/5 objective will show the corpuscles, but satisfactory work can be done only with an immersion lens. The percentage of hemoglobin can be determined within 10 per cent. by letting a drop of blood fall on white paper and comparing it with Tallquist's color scale, but it can not be obtained more exactly without a hemoglobinometer costing about \$40. The Thoma-Zeiss blood count apparatus may be termed indispensable and costs about \$15. Hardly necessities, the spectroscope and hematokrit, are the luxuries to be obtained as the fad grows on one. It may be said that \$25 will start one at work and \$100 more will be spent if his interest increases.

The third question that will occur to the general practitioner who determines to know something about the condition of the blood in his own cases is that of obtaining the technique. The very recent graduate is supposed to have acquired it. But we who took our degree before Ehrlich's writings had aroused general interest, must work out our own salvation with the myelocyte and megaloblast.

Fortunately, some good text-books have been recently published. Cabot is the best known. There is certainly no better book in English than the recent fourth edition. Stengel has a fine article in the "Twentieth Century

Practice of Medicine" and will soon issue a text-book; Ewing's "Clinical Pathology of the Blood" is recent and very helpful. For those who read German there is a large literature.

Personal instruction is most valuable and time-saving. But even for those who have neglected the subject altogether, patient labor will enable them to master the necessary details. The essential features are soon demonstrated; considerable practice is required to bring out all that careful staining may show.

As already stated, the necessary apparatus is a twelfth objective, a blood-count apparatus, a hemoglobinometer, an ordinary urinometer, and a few stains. With these we are prepared to obtain the specific gravity of the blood, to count the red and the white corpuscles, to arrive at an approximation of the hemoglobin percentage and to study smears.

The specific gravity is an important matter. Stern's paper before the association last year gave a hint of its meaning. The significance of variations in the specific gravity is not great in the diagnosis of disease which may be labeled. It may, however, reveal something as to defective oxidation, ability for physical labor, and resistance to infective processes. We may yet see life insurance companies requiring the specific gravity of the blood.

The method of Hammerschlag is accurate to one or two points and much cheaper than any other. All that is required is a good urinometer. In it chloroform and benzine are mixed in such proportions that a drop of blood neither rises nor sinks, when the specific gravity of the mixture determines that of the single drop of blood. Care must be taken that no air mixes with the blood drop, and the determination must be made before it becomes altered by the media. The instrument must also be perfectly dry that no water floats on top of the chloroform and is taken up by the blood. I have found the specific gravity varying from 1032 to 1062, so that a wide latitude exists. Excepting in dropsy, leukemia and pernicious anemia its variations correspond quite closely to the hemoglobin percentage.

The estimation of the bulk of red corpuscles is made by the centrifuge. It is quick and fairly accurate, and also corresponds closely to the blood count in many conditions, but not in all. It is well worth doing if one has the apparatus. The tubes are easily filled by capillary attraction if the outer end is held lower than the other, and they are kept clean by a horsehair.

That for hemoglobin is least accurate of all the tests. Observations are published in which variations of 1 per cent. are noted, but a margin of error of 5 per cent. at least must be allowed. It all depends on a color scale in the fine gradations of which the male sex is notably deficient. No standard yet manufactured is of the same shade as the blood when diluted; Miescher's is said to be the best instrument for its determination. Two plain indications are obtained by its determination: 1. A surgical operation should not be undertaken if the hemoglobin is as low as 30 per cent. Deaver, in a recent paper, cited two cases operated on successfully in spite of this rule, but still the rule holds as good as any in our art. 2. In diagnosis pernicious anemia is differentiated from cancerous cachexia by knowing that the hemoglobin ratio is higher than normal in the former and lower in the case of cancer. The grade of chlorosis and hence its chances of cure is determined by the hemoglobin test compared with the blood count.

The blood count is of importance in many ways. Extremely accurate work to be published requires the

counting of a large number of fields, but practical results are obtained in fifteen minutes.

A great increase in the number of lymphocytes means leukemia, which can be diagnosed in no other way than by the assistance of a blood count. A leucocytosis of from 12,000 to 50,000 means an infection, most often with formation of an abscess. Its importance in differential diagnosis is often second to no other symptom, but is never pathognomonic. Marked examples of its usefulness are in distinguishing appendicitis from typhoid fever, intestinal perforation in the course of typhoid, and the onset of pneumonia when the physical signs are masked. The opposite condition, leucopenia, is found most markedly in fatal septicemia. The diminished leucocytes may be as valuable as the Widal reaction in differential diagnosis of typhoid.

In considering moderate grades of leucocytosis the many physiological factors causing increase in the white corpuscles must be remembered. Cabot enumerates these agencies as the leucocytosis of the newborn, of digestion, of pregnancy, of the postpartum, of the moribund, and after violent exercise, massage and cold baths. These influences may raise the count normal to that individual 33 per cent. and must be kept in mind. The leucocytosis caused by anesthesia is so transient that it is not liable to confuse us.

In general it may be said that suppurative, serous and gangrenous inflammations produce marked leucocytosis. We must not forget that the leucocyte count falls when the abscess is walled off.

We are promised that the study of the leucocytes may be helpful in the prognosis of pneumonia. Absence of the usual leucocytosis looks to a fatal termination, while the return of the eosinophiles, absent at the height of the disease, foretells a favorable crisis.

A diminution of the number of red corpuscles is of great importance. It may be said that iron has frequently been given to a patient with white skin who had no anemia and derived no benefit from its use. The contrary is also true. A blood count furnishes the only rational data for the use of iron and arsenic. Pernicious anemia would be found in many cases supposed to be cancer of the stomach if the blood examination were more common.

The study of the stained specimen is the most interesting of all the steps in the examination of the blood. It is here that the novice will feel most intensely his deficiencies. Now his text-book directions fail him, and confusion, not wisdom, results from a multitude of counsellors.

His troubles begin with making the smear. But after one learns just how, it is easy to prick the ear quickly and deeply, to wipe away the first drop, to resist somewhat the temptation to squeeze out the blood that is so loath to flow when you want it, to touch to a very small drop a cover glass that has been carefully washed in soapsuds and alcohol and polished by rubbing. Upon this another is to be laid and the two quickly drawn apart by sliding. After drying in the air, which requires but a few moments, we must employ one of the many staining methods recommended. For the amateur it is better to use no more than one or two, and thoroughly familiarize himself with these. Cabot says that he now uses no other than Ehrlich's triacid stain. He tells us the trick of success with it, which enabled me to use it after I had given up the stain in disgust. The specimen must be thoroughly heated before it is used—heated until the blurred-brown color of the reds which

you get in underheating specimens, is replaced by a golden yellow. Then the details within the leucocytes will be found delicately differentiated.

The stain easiest to use is Gollasch's. The smear is fixed by immersion for a quarter of an hour in absolute alcohol, to which ether may or may not be added. The stain, which is composed of hematoxylin and eosin, is applied for fifteen minutes. If you are interrupted the specimen is not spoiled by overstaining, as occurs with the methyl blue and eosin methods. The white corpuscles are so plain that they are easily studied with a 1/5 objective. Goldhorn's polychrome stain, originally perfected for studying the malarial germ, has proved to be one of the best for general work; clear directions accompany it.

The study of stained specimens is eye-destroying and time-destroying work. Here it suffices to simply enumerate the details which a general practitioner may hope to see and what they may indicate to him. The red corpuscles may be deformed, not the result of faulty technique. This poikilocytosis means very grave anemia. The centers may not take the eosin stain, indicating a deficiency of hemoglobin, which is chlorosis or grave secondary anemia. The malarial germ may be seen. Nucleated red cells may be present—the blasts. Normoblasts mean a too active proliferation of red corpuscles, the marrow throwing them out unfinished. Megaloblasts are of grave import, indicating a fatal type of anemia.

Turning now to the white corpuscles, we notice the relative proportion of polymorphonuclear, lymphocytes and eosinophiles. Leucocytosis being already established by the blood count, an increase in the relative ratio of mononuclears would point to leukemia; in the polymuclears, to the leucocytosis of infection. Two types of leukemia itself are determined by studying the greatly multiplied white cells. The presence of myelocytes indicates the spleno-myelogenous variety, while the lymphatic is shown by the great number of lymphocytes. Iodophilia may reveal the presence of pus somewhere in the system. Eosinophilia may enable us to detect a case of trichinosis which has been called rheumatism.

My endeavor has been to show that the routine examination of the blood may be profitably made by the general practitioner.

## BRAIN TUMOR

DEVELOPING IN A CASE OF PERIPHERAL NEURITIS, THE  
LATTER OBSCURING DIAGNOSIS—OPERATIVE  
REMOVAL OF TUMOR—RECOVERY.

G. W. McCASKEY, A.M., M.D.,

AND

MILES F. PORTER, A.M., M.D.

FORT WAYNE, IND.

MEDICAL HISTORY AND DIAGNOSIS BY DR. McCASKEY.

H. C. B., aged 34, farmer, married, was referred by Dr. R. S. Wilson, of Berne, Ind., Sept. 8, 1900. The principal complaint was that of weakness and pain in the left leg, "heart trouble," and general nervousness, with severe pains in the head. Family history appeared clear. The patient's health had always been good previous to an attack of typhoid fever ten years ago. This in itself was uneventful excepting that it left some permanent damage to the digestive organs, and he has had some "stomach trouble since." About two years after the attack of typhoid fever he began to have pain in the calf of the left leg. This pain had continued since, growing better and worse, the patient insists, as his stomach grew better and worse. During these years he had been a constant sufferer from pain and extreme "bloating" after meals.

About six months prior to my examination, the pain in the

left leg became much worse and the weakness increased to such an extent that the hind was handled very awkwardly, and it frequently gave way, causing him to fall. The pain had also extended upward involving the thigh and hip, and had in addition appeared in the calf of the right leg. He had been a very heavy smoker, using about an ounce of tobacco daily. This may account for the heart disturbance.

There was decided parietic weakness of the left leg and arm. This was first noticed in the fall of 1899, and when husking corn, he had difficulty in breaking off the ear, owing to weakness of the left hand. At about the same time motor weakness of the left leg was manifested by a difficulty in handling the leg when wearing a heavy rubber boot. With a light shoe no difficulty was experienced. From this time on there had been a gradual increase in motor weakness, which became practically a complete paralysis in the left arm a few weeks later, and about the same time the left side of the face became very slightly parietic. The tongue and extrinsic eye muscles were unimpaired. There was no impairment of the sensorial function of the skin, excepting over the left leg from the knee downward. Over this area there was complete thermo-anesthesia, with marked impairment of tactile and pain sense. There had been neither tinnitus nor vertigo, and hearing was normal on both sides.

Vision was 18/20 for each eye—practically normal. The visual fields were carefully tested by the perimeter and found normal, in respect to the form, size, and relation of color fields. Ophthalmoscopic examinations showed the beginning of optic neuritis in the right eye, without protrusion of disc; later this became more marked, and appeared in the left eye.

The bladder sphincter was very weak. When he felt the desire to urinate he would frequently be unable to get off the porch into the yard. There was no impairment of rectal sphincter.

Owing to the history of the case a complete examination of the digestive organs, and general study of metabolism was considered necessary.

**Craniolysis:** Total quantity for 24 hours, 2400 c.c.; sp. gr., 1010; total solids, 55.92 grams; reaction, acid; no albumin or sugar; urea, 1.3 per cent., or 31.2 grams; uric acid, 1.73 grams; ratio of urea to uric acid, 30.1; total chlorids, 12 grams; there was no phenol nor skatol in pathologic amounts, but a very large amount of indican.

The blood examination showed 5,200,000 red cells, 105 per cent. of hemoglobin, with 6900 leucocytes, during digestion.

**Stomach:** In the fasting state, fourteen hours after the last meal, the stomach contained 20 c.c. of an amber-colored fluid, containing .09 per cent. of lactic acid, with epithelium, leucocytes, and a variety of microorganisms.

Quantity of gastric juice (Ewald test breakfast) obtained was 100 c.c.; no free HCl; faint biuret reaction; starch digestion complete.

Examination of colon contents showed a moderately severe chronic mucous colitis.

The case presented a "complication of diseases." The first coloring in the diversified clinical picture was the chronic gastro-enteritis which he received as a legacy from the typhoid fever. Following close on it were the phenomena of a chronic toxemia. Gastric motor insufficiency, with atrophy of gastric glands, easily gave the first link in the chain. At the time of my examination the main question of the diagnosis rested, of course, in the nervous system. There were indubitable indications of both peripheral and central disease, the precise nature of which was determined upon the following briefly outlined data.

Electrical examinations gave the following result: In right peroneus brevis and left gastrocnemius the galvanic formula was reversed. With 15 ma., and electrode of four square cm. area, a.c.c. > c.c.c. In all other muscles, c.c.c. > a.c.c., or in some, e. g., left gastrocnemius, were very nearly equal. In most of the muscles 10 ma.

gave quite as strong a reaction as 15 ma. in the two muscles above mentioned. The faradic response was notably lowered in all the muscles of the legs, most marked on the left side, while in the left gastrocnemius the tetanic contraction continued for some seconds after cessation of the current and required a current almost beyond the endurance of the patient to produce a contraction at all.

The combination of partial anesthesia, motor weakness, and the electrical reactions of degeneration in the left leg could leave no possible doubt as to the existence of a peripheral neuritis, which had to a less extent involved the right leg; and the origin of which could be most plausibly sought in the chronic toxemia resulting from gastro-intestinal disease.

The coexistence of motor weakness of the left upper extremity, however, without sensory or electric disturbances, showed that something more than a peripheral lesion existed, and presented a very difficult problem of diagnosis with reference to the paralysis of the left lower extremity, viz., was it exclusively peripheral, or was it also in part, and perhaps principally, a part of a hemiplegia of central origin? The supervention of parietic weakness of the left side of the face, which occurred later while the patient was under observation, proved the existence of a progressive lesion of the right motor area of the brain. After a careful study of all the data, the diagnosis of a brain tumor was added to that of multiple neuritis of toxic origin.

As the symptoms were growing progressively worse, I advised an operation, and the patient, still able to walk a quarter of a mile, entered the hospital for that purpose.

The operation was performed Feb. 6, 1901, by Dr. M. F. Porter, who removed, at my suggestion, a large quadrangular section of the calvarium, with the superior posterior angle just back of the upper end of the Rolandic fissure, and about one cm. from the sagittal suture, and the anterior inferior angle just behind and slightly below the stephanion. As it was nearly vertical, the location of these two angles will accurately indicate the field uncovered for the operative procedure.

I will discuss only a few points of neurological interest, passing for the sake of brevity many others that deserve attention. To aid in identifying motor centers when the bulging cortex was exposed, with no neoplasm in sight, I applied a pair of pointed wire electrodes, connected with a faradic battery, to the surface, and soon found the arm center. From this as a starting point the area of the leg center was thoroughly faradized without the slightest response. The subsequent steps of the operation showed that the tumor was for the most part directly beneath the leg center. It will be recalled that the paralysis of the arm, as usual in central lesions involving the motor area or tracts, was greater than that in the leg. The failure of the leg center to respond, under the circumstances, appears to me to be of considerable interest, and suggests the possibility of this test being available in exploratory operations to indicate the site of a suspected subcortical lesion.

There was absolute paralysis of the right arm and leg following the operation, but in about eight weeks the patient was able to walk out of the hospital, and motor power of the leg has slowly improved since, so that it is now much better than before the operation. The arm remains so weak as to be entirely useless.

Another phenomenon of considerable interest, although not at all new, was the extensive movements of the paralyzed arm, when the other arm was moved in the act of yawning or some similar general movement.

This occurred under my own observation several times while the arm was absolutely paralyzed so far as voluntary movements were concerned, the patient not being able to move a finger in the slightest degree. Such movements suggest some very interesting physiological questions, the discussion of which would be outside the intended scope of this essay.

The histological diagnosis was glioma, with apparent beginning sarcomatous degeneration, and, of course, a recurrence is anticipated. Sections of the tumor were examined under the microscope and show the structure of the neoplasm.

I will only refer to one other point, namely, the large size of the neoplasm, and the extreme pressure to which the right hemisphere and the ganglia were subjected, without permanent loss of function, although this was very nearly complete in the arm center. The median portion of the tumor had forced its way beneath the concave margin of the falx cerebri, and a considerable mass of it was removed from the left side of the cranial cavity. The finger was easily passed from the large space vacated by the tumor in the central region of the right hemisphere beneath the sharp concave margin of the falx, revealing a considerable space to the left of the falx.

#### OPERATION AND SURGICAL HISTORY BY DR. PORTER.

The operation was done at the St. Joseph Hospital. After the usual preparation the patient was etherized by Dr. B. V. Sweringer. A large horseshoe-shaped flap was turned down and a quadrangular section of bone removed, partly by the DeVilbiss instrument and partly by use of a Gigli saw. Nothing unusual was noticed through the dura, and it was therefore opened by turning a flap downward. The cortex presented nothing unusual to sight or touch. It was remarked, however, that the bulging of the brain showed an unusual intracranial pressure. On exploration with a needle a sense of increased resistance was imparted to the finger at a depth of about a half-inch below the surface. This could be felt at several points, and thus it was proven not to be due to accidental contact with a blood vessel. The finger was now introduced and passed around the tumor, which proved to be ovoid in shape, of a trifle greater consistency than the brain with a capsule of slight resistance, which could easily be separated from the surrounding brain, but not without producing free hemorrhage. From the falx cerebri the tumor was separated by a very thin stratum of brain tissue above, but was in contact with and passed under its lower border, extending fully a quarter of an inch to the left of the middle line. The tumor was about the size of a pullet's egg. Owing to the friability of the capsule and also because of a desire to minimize the amount of injury done to the brain, the tumor was removed piece-meal. The hemorrhage, which was free, was controlled by gauze packing. The bone was not replaced. The dura and scalp were sutured save at point of exit of gauze and a dry dressing applied. At the end of 48 hours the packing was removed and a wick of gauze placed for drainage. This was removed a few days later. The wound healed without suppuration, and from a surgical standpoint the recovery was uneventful. The man was cured at once of head pain, regained full use of his leg, and is able to raise the paralyzed arm to the head. I am informed by his family physician, Dr. Wilson, that at the present writing, Nov. 9, 1901, there is some return of head pain and that there are present some mental symptoms. These symptoms indicate a recurrence of the growth, which was predicted at the time of the

operation. On December 27 I was informed by Dr. Wilson that the head pain and mental symptoms had entirely disappeared and that in his opinion the patient would make a permanent recovery. More time must elapse, of course, before this question can be settled.

I wish to refer to but one point in the technique, and that is the use of the Gigli saw. For removing large sections of the skull I regard it as superior to any other instrument. For removing quadrangular flaps four small openings are made with a trephine, the end of the saw is passed between the dura and the bone from one opening to the other, caught by a pair of forceps or hook, pulled out and the intervening bone sawed through. This is repeated until the section is completed. If one wants to do an osteoplastic operation the bone may be sawed through, except at the base where the internal table alone may be divided, thus facilitating fracture and insuring against the possibility of immediate or late untoward effects from spicules of bone. The saw lends itself admirably to the removal of sections of any shape save those having curved borders. Aside from the ease and rapidity gained by the use of the saw, there is no hemorrhage from the diploe divided by it.

### SURGICAL CORRECTION OF MALFORMATION AND SPEECH DEFECTS DUE TO OR ASSOCIATED WITH HARE-LIP AND CLEFT PALATE.\*

GEORGE V. I. BROWN, A.B., D.D.S., M.D., C.M.

Professor of Oral Surgery, Milwaukee Medical College, and Oral Surgeon, Trinity Hospital.

MILWAUKEE, WIS.

(Concluded from page 172.)

#### ADULTS AND CHILDREN WITH PERMANENT TEETH.

The treatment of cases of the fourth class—shown in Figs. 14, 15, 16 and 17, all of the same case—is in all respects practically the same, except that the appliance needs to be made of strong material, because permanent teeth form points of attachment and older jaws give more resistance. When it is desired to hasten the contracting process, the patient is anesthetized and the surgical engine bur passed along the posterior portion of the buccal side of the jaw just under the teeth and the external plates of the maxillæ cut through, this being the point at which the greatest resistance is offered, and when weakened in this manner pressure is made by the use of suitably adjusted forceps, which bring the two sides as nearly together as possible without complete fracture. The appliance and screw hold the parts in place, and continuous turning of the nut quickly brings them in close approximation from the bicuspid forward, altering the occlusion of the jaws so that upper molars, instead of occluding with buccal cusps outside the buccal cusps of inferior molars will meet upon the inside. The width of a molar tooth can be taken from the width of the space between the bones at the fissure without interfering with the proper performance of the function of mastication, and all who are familiar by practical experience with cases of this character will readily understand what a considerable difference the width of a molar tooth less space to cover must be in relation to successful results, so far as securing a covering is concerned, and also for having less tension of soft palate tissue in the effort of speech. The principles of this method have long been followed

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee.

by orthopedic surgeons in the treatment of malformation of other bones and by dentists in correction of irregularities of the dental arch. What is claimed for the method outlined is that for the first time systematic application of all these principles has been combined

ing thus supplied a covering for the roof of the mouth of living, healthful tissue and the same for the soft palate, that a marked improvement in speech would be expected, yet this is not so, and the question as to "why it is not so" embodies in itself many considerations. While

Figure 14

with methods of surgical procedure which make it possible to operate with comparatively complete success upon all cases without regard to age or the nature of

Figure 15

the cleft, provided there be no serious physical bar to operation. If then this can be done at practically any age, it becomes important for us to consider all these matters in relation to results from the standpoint of acquiring perfect speech. It naturally follows that hav-

Figure 16

flexibility of the velum after operation and absence therefore of scars with cicatricial tissue to stiffen and to interfere with the muscular movements are desirable, even indispensable for its perfect vocal assistance, the

Figure 17

real reason why the speech of adults improves so little is the same as that which causes an American to find it difficult to speak French, German or other foreign language, and when he does so to think the sounds that he makes the same as those made by natives in pronounce-

ing the same words, for he is conscious of no distinguishing difference, whereas differences do exist in a marked degree and are quite noticeable to other people. There are several elements in the explanation of this fact that are worthy of consideration and lead us directly to a

Figure 18.

study of the mechanism of speech. To get perfect speech as a result of palate operation we must, 1, supply tissue, which will serve to prevent the nasal sound by shutting off the nasal passages at the proper time; 2, the

Figure 19.

ear must become so trained as to distinguish readily incorrect sounds in the pronunciation of words; 3, the brain centers which receive the impressions that excite sound vibrations must carry to the motor centers messages that will set the right muscles in action in the right way. Invariably with older patients is it found that efforts to speak in spite of the cleft palate deformity

have caused greater development of muscles, the application of which are usually a hindrance instead of a benefit.

#### SPEECH CENTERS.

The so-called area of speech as commonly conceded involves something more than a distinctly outlined portion of the brain structure, but in a general way it may be understood that in and about the Sylvian fissure, the third frontal convolution, the Rolandic area, and that particular portion known as Broca's convolution, the various psychomotor centers necessary to vocalization are located, and a consideration of the association of these parts to each other will convince the careful reasoner that in the correction of these oral deformities there are many difficulties to be considered beside merely the task of securing an adjustable veil which will serve to close or open certain air passages during the act of speech as in the normal individual. A study of the brain

Figure 20.

structure and of the principles upon which modern brain surgery is based, proven over and over again through experiments upon lower animals and by clinical experience in the study of aphasia and other affections of speech due to diseased conditions, makes clear the fact that the perfect formation of words and their construction into intelligent sentences requires the coöperation of many distinctly different nerve centers.

The first cry of the child is merely a sound caused by reflex action of the muscles without any guiding influence exerted by the faculty of reason. This is followed by the first efforts of sound to represent intelligent words as objects begin to be recognized, and gradually this is continued and extended until expression of ideas in speech has become possible. It will be readily understood that if these efforts have been upon normal or correct lines, the muscular activity necessary to sound producing must have been guided by the proper nerve centers, which will have caused an increase in the brain development of those centers, and the messages sent

from the motor tract to the muscles which are concerned in the utterance of words will be in all respects correct, therefore, the habit of proper speech will have become an established fact, but, on the other hand, if a deformity has existed from birth by reason of which the normal use of certain muscles will have been greatly restricted and the use of certain other muscles not commonly used in the process of word enunciation, it will have received more stimulation than would have been the case had there been a perfectly formed mouth and throat. The result must invariably be an increased development of the nerve centers which are injurious to speech, with a faulty development of those that are necessary to perfect speech. This would be termed a habit, but the word habit conveys too restricted an idea of the condition. For example, when the eye through its retinal image registers upon the brain structures the particular nerve stimulations which in time shall become associated with the name of an object, its form record is established by

Figure 21

what may be known as the visual memory centers. In the same manner the sound of the name of the subject through vibrations of the auditory nerves, and organs of hearing becomes fixed in the auditory memory centers. Precisely also are the somesthetic areas affected by the tactile sense, and memory of the sense of touch, as well as taste, smell or other stimulus that may have been excited by or associated with any particular object, and when the sensorium takes consciousness of this object, the name of which has become known to it, there is required the coordination between these different memory centers in order that the proper messages may be sent to the motor centers through which certain muscles may be set in motion in the proper manner to produce the sound which may be clearly recognized as the spoken name of the object.

It is known that in speech the muscles of the chest which are responsible for expiration, the muscles that raise and lower the larynx, those that tighten the vocal cords and tip the hyoid bone, as well as resounding

properties due to the nearness of the spinal column, and the cooperation of the forces that are applied in raising and lowering the soft palate, the adjustment of the tongue, proper action of the muscles of the cheeks and

Figure 22

lips are all necessary for the utterance of even a single word. If, therefore, during the life of the individual, through faulty operation or adverse action of these agencies, wrong messages have been constantly sent to

Figure 23

any portion of the brain concerned in making a certain sound, and if the auditory memory centers have registered by the constant hearing imperfect sounds for specific words, which will accordingly have caused the devel-

opment of brain structure which is all active against correct speech, and if there be an insufficient development of those centers which are needed for perfect speech, how great becomes the difficulty of giving a speech power to individuals in the face of all these acquired disadvantages.

It is too narrow a view of his own special portion of the sound-making apparatus that has so limited the oral surgeon in his consideration of this subject in the treatment of cleft palate. There has been laid down the absolute necessity of having a soft palate which will be capable of entirely excluding the passage of the air to the posterior nares, thus to overcome nasal tones, but a well-known writer has recently stated that this is a false idea, since there are many times in speaking and singing, during which the passage of the air through the nares is not excluded, and yet no nasal tone is noticeable. As a matter of fact both the quality and tone are largely decided before the sound wave has reached the soft palate.

Practical examples of the truth of these theoretical principles are shown by the following illustrations. Figs. 18, 19, 20 and 21 show photographs and casts of the mouth of a patient before and after operation. The cleft was confined to the soft palate alone.

Figs. 22 and 23 show a very large cleft extending through both hard and soft palates. These patients are girls and about the same age, yet the speech of No. 22, with a much greater deformity, was somewhat clearer than No. 18 before operation, with a smaller opening in the palate. This is particularly interesting because an unusual development of the muscles that raise the tongue and constrictors of the pharynx had enabled No. 22 to force the back of the tongue up into the cleft and narrow the pharyngeal opening so as to overcome in a measure at least the deficiency, but the unusual muscular action will undoubtedly militate against success after operation when case is completed. No. 18, having been given almost a perfect velum—see Figs. 19 and 21—one quite flexible and free from the thickening of scar tissue, while much improved in ordinary conversation retains a good deal of the characteristic disagreeable vocal sounds, and when excited becomes almost unintelligible, yet when reciting a little piece that I have recently taught her to say properly, the involuntary office of wrong auditory and other memories being by effort excluded, she has nearly perfect vocalization, marred only by a slight nasal tone not more than many persons with normal palates acquire through catarrh or habit, and thus we have clearly established the fact that only a few weeks after operation it is possible with a little care to get nearly perfect speech. A summary of conclusions from the foregoing would be as follows:

1. The risk of operation in early infancy is unnecessary except where vitality of the child is threatened by malformation.

2. The most favorable time for operation is after the deciduous teeth have been erupted, but before the habit of speech has been acquired.

3. Difficulty of acquiring correct methods of pronouncing words after operation in adult cases can only be overcome by careful mental training.

4. There can be no cases which can not be improved by treatment and operation, both with regard to health and speech, no matter what the age may be, providing the coöperation and assistance of the patient may be assured.

#### OPERATIVE TECHNIQUE.

The post-operative treatment of these cases presents certain difficulties a due regard for which is essential to success. Wounds of the mouth, however great may be the antiseptic precautions at time of operation, are always in greater or less degree subject to infection by mouth bacteria, the tissues of the approximating surfaces in uranorrhaphy and staphylorrhaphy have, in addition to bacteria-laden buccal fluids below, nasal secretions above in direct communication without the possibility of protection by any form of dressing; moreover, the tension upon sutures in such cases and the tendency to tear or slough out renders every possible precaution, tending to the preservation of the integrity of the parts imperative to the last degree. Powerful germicides are excluded, owing to their toxic properties and the impossibility of preventing them from being swallowed if freely used for irrigation: many of less germicidal strength, but otherwise harmless, are useless because of unavoidable dilution in the mouth.

Escarotics are obviously to be discarded as destructive rather than favoring the process of granulation. My own practice is as follows:

Preparation is by irrigation of both oral and nasal cavities with boracic acid solution, thorough wiping of mucous membrane surfaces with sponge and 3 per cent. carbolic solution. After-treatment consists of cleansing the mouth every half-hour alternately with dioxogen and sterilized water, in infant cases, while for adults dioxogen and 3 per cent. carbolic are alternated every half-hour. These are applied with a small glass syringe, and by the use of little swabs made of absorbent cotton rolled upon toothpicks for convenience. Dioxogen is immediately effective, is non-toxic, and has the valuable property of freeing by its action the dead mucous cells and animal fats that cover the mucous membrane of the mouth and resist complete destruction of germs thus protected unless some agent be applied which will mechanically cleanse and effectually remove them.

Infants suck at or attempt to swallow everything that is put into their mouths, therefore it is impossible to use any solution constantly without more or less being taken into the stomach. Dioxogen and sterilized water are beneficial rather than harmful, but if poisonous drugs were used the danger would unquestionably be a serious one.

NOTE.—I have found it necessary to use the term dioxogen, as indicating a preparation of  $H_2O_2$  of unquestioned purity, because a quotation from a former paper was printed and scattered broadcast without my knowledge or consent by the manufacturer of a preparation of  $H_2O_2$  that I would under no circumstances feel it safe to use in cases when acid impurities might be seriously injurious, as would be the case in any but more particularly with infant patients.

#### Prevention of Precipitation of Oxalates in the Urine.—

Klemperer states in the *Berl. Klin. Woch.* of December 30, that it is not necessary to banish the oxalates from the urine to prevent the formation of oxalate calculi. This can be accomplished by merely rendering the urine able to keep them dissolved. He announces that when the urine contains a certain proportion of magnesia, there is no precipitation of oxalates, as they are dissolved by the magnesia. The food should contain little lime and considerable magnesia. Milk, eggs, tea, cocoa, spinach and cabbage should be avoided in cases where there is a tendency to oxalate calculi. The diet should consist of meat, fats, bread, farinaceous foods, rice, peas, beans, apples and pears, with considerable fluids. The oxalate tendency does not contra-indicate alcoholic drinks nor coffee. This diet can be supplemented by more magnesia, as for example, 2 gm. of the sulphate a day.

# TRAUMATIC ARTERIO-VENOUS ANEURYSMS OF THE SUBCLAVIAN VESSELS.

WITH AN ANALYTICAL STUDY OF FIFTEEN REPORTED CASES, INCLUDING ONE OPERATED UPON

RUDOLPH MATAS, M.D.

NEW ORLEANS.

(Continued from page 176.)

## HISTORY SUBSEQUENT TO OPERATION.

The subsequent career of this patient after the operation was marked by many incidents which delayed his convalescence and caused us much anxiety as to the ultimate fate of his arm, but never gave us serious apprehensions as to his ultimate recovery.

Some idea may be obtained of the tediousness of his convalescence by noting that he was admitted to the hospital on September 8 (fifth day after the injury), was operated on September 13 (ninth day), and was discharged Nov. 12, 1900 (sixty-first day), and even then his arm had not healed, and he was not entirely discharged by Dr. Power at his home until April 19, 1901 (158 days after leaving the sanitarium), when he discarded his last dressings. He was, therefore, under treatment a little over seven months from the date of the operation. It is just to state that this delay in his complete recovery was caused almost entirely by the sloughing which took place in the hand and forearm, which followed immediately after the ligation of the artery. The wound in the neck healed *per primam*, and never gave us the least anxiety. With the exception of a stitch abscess it healed without interruption and was entirely well on the twenty-second day, when all dressings were discontinued in the neck. The necrotic changes that took place in the hand and forearm are of such rare occurrence after ligations of the subclavian vessels that they deserve special reference in this history. My notes in reference to this point read as follows:

September 14, 9 a. m. (the day after the operation), patient's general condition much improved. Pulse, 110; temperature, 99.5. Patient complains of little pain in region of wound, which, in addition to copious aseptic dressings and spica bandage, has been covered with a square flat bag filled with bird shot, weighing half a pound, to further compress the part and favor the obliteration of dead spaces.

The cotton batting and loose bandage are removed from the arm, and I am painfully surprised to find evidences of complete mortification of several digits and parts of the palm of the hand and forearm; the skin in some places on the ulnar side appears to be necrotic up to the elbow. Complete insensibility of the entire extremity up to the bend of the elbow exists. After washing the extremity in hot water and alcohol, the capillary circulation is found to exist in considerable areas over the dorsum of the hand, wrist, and forearm; but the palm and fingers, especially the little finger and the thumb, appear to be hopelessly lost. No radial, brachial, or axillary pulse can be felt. The arm down to the elbow is sound, warm, and sensitive. The hand is shriveled, pale, waxy, cadaveric; here and there a few patches of capillary extravasation or stains; no swelling, edema or violaceous discoloration; no signs of venous asphyxia; the superficial veins, which before the operation were prominent and turgid, had now become invisible. The mortification is evidently due to arterial ischemia. Arm wrapped up loosely in cotton batting and surrounded with hot bags.

At 3 p. m. the temperature had risen to 101; pulse, 136. Evidently the reactionary changes due to the sloughing were causing the disturbance, because there was nothing in the wound to account for the change. At 4:30 p. m., pulse 130; at 7:30, pulse 128, temperature 101, skin moist, general condition excellent. The

hand, at wrist and forearm, is now beginning to show edema, and there are dry patches of dark extravasation over the mortified areas. The arm above the wrist and elbow and in proximity to the dead parts is hot and presents a dusky red erythematous color.

On September 20 the following observations are recorded:

The affected arm is still much swollen and edematous, though the swelling is now subsiding. The thumb nail and skin in palmar and dorsal aspects of the thumb mummified, shriveled, dry, purplish black in color; tip of index finger and nail, black and dry; ring finger to first knuckle black; two large black, dry patches in palm of hand and base of thumb; another large, black, leathery patch over the entire hypothenar region. A large blister has formed extending over the ulnar and dorsal aspects of the forearm.

The arm was treated by daily washing with hot lysol solution—1 per cent.—followed by complete alcohol bath, after which it was thickly covered with an ointment consisting of ichthyol and zinc oxid and vaselin; over the forearm and arm; where the skin appeared to be red and inflamed compresses of dilute lead and opium lotion were kept constantly applied. On September 28 I left the city for a month's vacation and transferred the patient to Dr. Gessner, who continued to attend and dress him carefully until my return, October 31, when the following observations were noted:

General condition excellent; temperature and pulse normal; good appetite; patient sits up. Wound in the neck completely healed since September 20, requiring no dressing. The most important changes have taken place in the hand and forearm. The little finger had dropped off, leaving a large granulating surface in the hypothenar region; a large granulating surface over the thenar eminence, where the skin had also sloughed off. The thumb had sloughed and had to be excised. The first metacarpal is exposed on the palmar side. A deep palmar tunnel connects the granulating surfaces on the two sides of the hand. This tunnel in the palm is caused by the sloughing of the long flexor tendons and some of the interossei. The ulna from its upper third down to the wrist-joint is exposed, even the periosteum being lost. Only the styloid process and articular end are sound and covered with soft parts. All the pronator-flexor mass of muscles and other soft parts covering the ulna have sloughed off, leaving a granulating tissue on the periosteum, apparently trying to cover it. A long sinus, caused by the sloughing of the supinator and extensor muscles and brachialis anticus, can be traced upward into the lower third of the arm. Four and a half inches of necrotic ulna were excised with the Gigli saw; the first metacarpal was enucleated out of its periosteal shell. The nail and terminal phalanx of the index were removed; the gaps in the palmar side were covered over with dorsal cutaneous flaps. A free incision was made from the forearm to the arm into the external intermuscular septum to remove the sloughs formed by the supinator and the brachialis anticus; the musculospiral and ulnar nerves have been lost in the deep sloughing of the forearm; there is complete anesthesia of all parts below the elbow.

After this the condition of the arm steadily improved, and the patient was discharged November 12, in very good general condition, but still suppurating through several granulating sinuses. After this, his arm was attended to at his home by Dr. Power, who had to open another sinus resulting from extension of suppuration in the arm. He also wrote that the wound in the neck had reopened at one point for a few days, but had healed without discharging any ligatures.

Finally, when the patient came to see me, April 19, his arm was entirely healed and presented the appearance shown in the photograph. He had lost his thumb and little finger, and the remaining digits were living, but stiff, rigid, and completely anesthetic. He has a stiff

wrist and a much reduced forearm, the ulna being wanting. Nevertheless, he has slight supination and pronation, caused by preservation of the biceps tendon, and has fairly good motion at the elbow. The skin is devoid of sensation up to the elbow.

#### SUMMARY.

In closing the description of the case we would call attention to the following points:

1. The lesion caused by the bullet was a true aneurysmal varix of the middle third of the subclavian artery and vein just where the vessels are separated by the musculo-aponeurotic partition formed by the scalenus anticus.

Case of Morse M.—Arterio-venous aneurysm of the right subclavian vessels; from photograph taken after complete healing of the wound and sloughed surfaces had taken place. The deformity resulting from sloughing of the forearm and hand is shown on the arm (right) paralyzed by the injury.

2. A continuous direct channel had formed between the artery and vein through the small perforation in the muscle.

3. The early establishment of a communication between the artery and the vein was favored in this case by the primary hemorrhage, which immediately filled up the rigid and unyielding space between the scalenes and forced the artery against the posterior surface of the muscle, thus compelling the stream of blood to escape through the small perforation made by the bullet, and directing it in the line of least resistance—*i. e.*, toward

the opening in the vein, which was held against the anterior surface of the muscle by the clot which accumulated in the space bounded by the scalene, clavicle, and deep cervical fascia.

4. The stream of arterial blood in the subclavian artery had been almost completely short-circuited and was poured into the proximal or cardiac side of the subclavian vein, which was enormously distended thereby, the circulation of the upper extremity being kept up chiefly by the collateral circulation.

5. A simultaneous contusion and injury of the brachial plexus existed, which led to a paralysis of sensation and motion, which was intensified by arterial ischemia of the arm.

6. The dissection and elevation of an osteoplastic flap, including the inner two-thirds of the clavicle, was most advantageous in securing a free access to the injured parts.

7. The innominate artery was missing, and in its place an anomalous subclavian, originating from the arch of the aorta, existed; the corresponding common carotid, originating in the arch on the left side of the trachea, did not reach the surface until it had ascended to the lower level of the thyroid gland.

8. The provisional loop of silk applied around the origin of the subclavian to secure prophylactic hemostasis in the field of operation, failed to control the bleeding from the proximal side of the arterio-venous orifice when the vein was detached.

9. Bleeding from the subclavian at the aneurysmal orifice was only controlled after the artery had been secured by a double ligature applied on each side of the bleeding-point—*i. e.*, on the inner and outer side of the anterior scalene.

10. In future operations in similar conditions the only means of securing absolute prophylactic hemostasis, that is, on the arterial side, would be to resort to digital compression over the subclavian artery at the origin of the vertebral—just below the tubercle of the fifth cervical vertebra—in addition to the traction loop of silk applied around the innominate. The application of a traction loop on the first portion of the subclavian on the outer, or axillary, side of the origin of the vertebral is a procedure beset with many difficulties, because of the numerous enlarged and adherent veins which are matted together in a mass of exudates and which would flood the field at the least provocation. Digital compression of the vertebral could be readily and effectively applied, while the innominate, which as a rule is quite accessible, would be compressed by the traction loop.

11. It is possible, as shown by this case, to restore the continuity of the subclavian vein by lateral suture after detaching it from the aneurysmal orifice.

12. The possibility of mortification of the peripheral part of the extremity must not be overlooked in considering the prognosis and post-operative results.

13. This ischemic necrosis of the extremities is more liable to occur when the subclavian is subjected to torsion in its second division, thus probably obliterating or injuring the orifices of the thyroid axis, vertebral and other branches.

14. The partial mortification of the hand and forearm in this case, while traceable directly to the arterial ischemia, was probably favored by the defective innervation of the parts from injury to the brachial plexus.

15. A notable feature of the sphacelation was that it especially involved large muscular groups rather than the overlying skin, thus confirming the observations of

Lesser, Volkmann, Ludwig, Bernays and others on the degenerating and necrobiotic effect of arterial ischemia upon muscular tissue.

16. The advantages of massive infiltration with very dilute cocaine and cocaine solutions were well shown in this case, as they economized the use of the general anesthetic and permitted not only the painless resection of the clavicle, but also facilitated the exploration of the deep cervical blood vessels, while applying a traction loop of silk around the anomalous subclavian at its origin.

17. When a general anesthetic becomes necessary, chloroform, preceded by morphin, is, in these cases, better than ether, because it is not accompanied by as much respiratory disturbance and overdistension of the veins.

18. The experience of the author in this case confirms his previous observations and those of others—Cushing, Lohenthal, Jaboulay, etc.—to the effect that the preliminary administration of morphin, followed by local infiltration, apparently predisposes to the favorable and economical administration of chloroform, which, in this case, was never pushed to absolute unconsciousness.

#### HISTORICAL DATA.

The history of arterio-venous aneurysm clinically begins with the first accurately recorded case, described by William Hunter in 1757, and anatomically by the description of Delaunoy in 1761, which was based on the postmortem study of a lesion implicating the femoral vessels—Broca. The first accurate account of arterio-venous aneurysm of the subclavian vessels dates back to the classic case of the Sargent Pierre Cadrioux, whose injury was treated by the distinguished Dominique J. Larrey in 1829, and made memorable by his admirable description of this condition.<sup>3</sup>

From 1829 to the present time we have been able to gather the records of 15 cases of arterio-venous aneurysm, including our present observation. The recorded traumatism of the subclavian vessels are rare, not only because these vessels are well protected by the clavicle, and are not so much exposed to injury as those of the extremities, but chiefly because accidental injury to these vessels is so liable to a promptly fatal termination from associated complications, and the profuse primary hemorrhage and shock, that the patients do not survive long enough to be subjected to any form of surgical treatment. Nevertheless, in 1877, Von Bergmann was able to collect 90 recorded instances of gunshot and stab injuries of the subclavian vessels. Rötter, of Berlin, as near to us as 1893, was able to collect only 11 cases of stab wounds of the subclavian vessels; and Souchon, in his remarkable essay on the surgery of the subclavian artery, published in 1895, was able to collect only 11 cases of arterial traumatic aneurysms, all involving the third division of the right subclavian.

Our collection of 15 cases of arterio-venous aneurysms, gathered from all sources in the literature, are all traumatic, and include injuries to the vessels on either side, irrespective of the topographical division of the artery involved, though, in a large majority of these, the precise point of injury could not be accurately ascertained.

The cases are reported in chronologic order by the following observers: 1. D. J. Larrey, Paris, 1829; 2. Sanson, quoted by Robert, Paris, 1832; 3. Bérard, quoted by Richet, Paris, 1842; 4. Wattmann, Vienna, 1843; 5. Wederstrandt, New Orleans, 1854; 6. R. W. Smith, Dublin, 1860; 7. Fischer, Göttingen, 1861; 8. Letenneur,

Santes, 1861; 9. Will (J. C. Ogilvie), Glasgow, 1875; 10. B. Kirsch, Breslau, 1875; 11. A. P. Arango, Medellin, Spain, 1880; 12. J. V. Rötter, Berlin, 1893; 13. G. Wedekind, Berlin, 1893; 14. Veiel, Cannstadt; 15. Matas, New Orleans, 1900.<sup>4</sup>

The reports of these cases, together with the comments of the authors and the important discussions which followed the presentation of several of these to various medical societies, furnish the available data upon which the special history of this rare, interesting, and serious lesion is based.

#### ANALYSIS OF CASES.

An analysis of these 15 cases furnishes the following points of interest: 1. Nine were caused by stab or penetrating cut wounds; 6 by bullets. 2. All the patients were men. 3. The injuries were almost all inflicted upon comparatively young subjects. Of the 9, whose ages are distinctly specified, the oldest was 32 years of age at time of injury; the youngest 15 years. In 6 cases the ages are not specifically stated, but the evidence would point to the fact that none had exceeded the middle period of life. 4. In 6 cases the vessels on the left side were injured; in 7, those on the right; in 2, the side injured is not stated. 5. The seat of injury was absolutely demonstrated to be in the subclavian vessels in 7—Wattmann's, Wederstrandt's, Will's, Rötter's, Wedekind's, Veiel's, Matas'—either by autopsy or operation. 6. In all the cases but 2, in which the seat of the lesion is either positively or approximately stated, the third division outside the scalenus was implicated. In Letenneur's case injury of the first division was suspected. In the author's, the second division was positively involved.

In the 8 other cases the diagnosis of injury of the subclavian vessels was confirmed by the seat of the external lesion, course of weapon, and range of the missile, the tumor, the immediate effect upon the circulation of the arm, and the other physical signs, showing that the subclavian trunks, and not their branches, had been injured.

In 5 of the 15 cases the brachial plexus was coincidentally and partially injured: positively in 3—Larrey's, Wederstrandt's, Matas'; probably in Letenneur's and Kirsch's cases. In several cases, in which reference to the condition of the arm is made, the disability of the arm was pronounced, but was either due to primary or secondary vascular disturbances—Wattmann (secondary), Smith, Arango, Wedekind, Veiel.

Primary circulatory or neural disturbances may have existed in other cases, but this can not be stated from the published reports.

The time after the injury, when the first sign of arterio-venous aneurysm was first recognized, is stated in 8 out of the 11 unoperated cases; in 3 it is only approximated; in 1 the characteristic thrill and murmur were apparently altogether missing—Will's case; in 3 no information on this point can be obtained. In 1—Matas'—the signs of arterio-venous communication were established within four hours after the injury; in 3 cases they were present on the second day—Larrey, Wederstrandt (?), Rötter; in 3 the diagnosis was made on the third day—Letenneur, Kirsch (?), Wedekind; in 1 on the sixth day—Fischer (?); in one on the eighth day—Arango; in one on the ninth day—Veiel; in 1 "a few days later," after the injury—Bérard's case.

4. To these fifteen cases two more should be added, viz., Reboul's, Montpellier, 1894, fatal, not operated; Vallas', Lyons, 1900, fatal, operated; both caused by indirect fracture of the clavicle; in all, seventeen cases.

3. *Cliniques Chirurgicales*, Paris, 1829, vol. III, p. 115.

Apart from injury to the brachial plexus and purely vascular disturbances in the arms, complications are noted in Wattmann's case—secondary phlegmonous inflammations of arm; in Will's—septic hemopyothorax; in Wedekind's—septic phlebitis and pneumonia. In only 3 of the 15 cases did secondary hemorrhage follow after the primary injury, and these were all stab wounds—Will, Rötter, Veiel.

Of the 15 cases 11 were treated expectantly, and of these 1 died from secondary hemorrhage and septic complications three weeks after the injury, and after the external wound had healed—Will's case. The remaining 10 all survived the immediate effects of the injury, their wounds healing after the cessation of the primary hemorrhage.

Only 4 out of the 15 cases were operated upon; in 3 of these—Rötter, Veiel, Matas—within twelve days after the injury, and all recovered; in 1—Wattmann's case—thirty-two years after the primary injury, when the ligation of the subclavian was necessitated by urgent aneurysmal complications, and this was the only fatal case. The total mortality of the entire group is, therefore, 13 1/3 per cent.<sup>5</sup>

An investigation of the individual records as far as they are available shows the following results as regards the final outcome of this injury on the vessels and upon the affected arm:

1. In Larrey's case—saber cut—four years after the injury there was marked diminution in the aneurysmal signs, but the arm was disabled completely by paralysis, contracture of fingers and hand, the pulse in the brachial and radial vessels suppressed, and the circulation in the superficial veins obliterated.

2. Sanson's patient—gunshot—quoted by Robert, was living ten or more years after the injury, but still annoyed by a loud, purring murmur (ronflement) and other active signs of aneurysm, which could be heard at a distance, and for which he consulted Sanson.

3. Bérard's case, quoted by Richet—stab—left the hospital "several weeks" after the wound had healed, but complaining of the annoyance caused by the disturbing noises in the aneurysm. These seemed to exasperate him, and he clamored for an operation, which neither Bérard nor Dieffenbach would perform.

4. Letenneur's patient—small pistol shot—healed, with persistence of all the aneurysmal signs, but felt well and was able to take his first promenade twenty-one days after the injury, after which no further observations are recorded.

5. Wederstrandt's patient—shot—recovered from his injury, and died at the Charity Hospital seven years after, from diarrhea. He had marked aneurysmal symptoms, with paralysis and atrophic changes in the arm, up to the time of his death, and at the autopsy a well-marked varicose aneurysm between the subclavian artery and vein was found.

6. Fischer's case—stab—recovered from the injury, with persistent signs of aneurysm, but was living one year after the injury, after which he passed out of observation.

7. Kirsch's patient—shot—recovered from the immediate effects of the injury, remained under observation two and one-half months, but was not improved, was discharged with active aneurysmal signs. He suffered also from persistent disturbances in the circula-

tion, and innervation of arm and hand: he had difficulty in moving his fingers.

8. Smith's patient—stab—recovered from the immediate effects of the injury, the wound healing in three weeks. Signs of varicose aneurysm existed seven months after the injury, with disturbances in the circulation of the arm under certain conditions. Eight months (?) after the injury he was compelled to return to the infirmary, with signs of obstruction in the circulation of the arm. The arm on the affected side had suddenly become cold and edematous, and in a few days gangrene of the ring and little finger, with part of the forearm and hand, had set in. He gradually recovered from the sloughing without serious constitutional disturbance. The radial pulse, which had ceased to beat from the time of the injury, now, strange to say, returned, when gangrene was established. The aneurysmal signs still persisted actively when discharged.

9. Arango's patient recovered from the immediate effects of the injury, which was accompanied by marked circulatory disturbances in the arm, but no sloughing. He was so much disturbed by the noises in the aneurysm that he had to be carried to the vicinity of a torrent in order to drown the sounds and thus secure sleep. This intense disturbance subsided in forty days. Two months afterward the aneurysmal signs continued, though much diminished. Ten years later, the patient's friends reported him "feeling perfectly well."

10. Will's patient—stab wound of subclavian vessels complicated by perforation of pleura—was stabbed on May 7, 1875; left hospital May 19, had first secondary bleeding while traveling; May 25, last and fatal hemorrhage. Patient expired as the operator had begun an incision to expose the bleeding vessel.

11. Wedekind's patient—stab—recovered from the immediate effects of the injury and was in excellent general condition seven months after, but the aneurysmal signs remained unabated, and he suffered, under special conditions, from transitory disturbances in the sensibility of the arm and hand, caused apparently by interference with circulation.

Under the category of unoperated cases we could also properly include Wattmann's case. This case is most interesting as showing that even after a latent period of thirty-one years, in which the patient was apparently well, the lesion finally became active and gave rise to fatal complications.

Thus we find that in 11 out of 12 cases which were treated primarily by the expectant plan, 11 recovered from the immediate effects of the injury, and their wounds healed without secondary hemorrhage, except one—Will's case—by simple measures of compression with bandages, rest, etc. But it is to be noticed, also, that only in one or possibly two—Larrey and Arango—was there reason to believe that the lesion had been cured. In all, the signs of arterio-venous aneurysm remained active, and in several the murmurs and sounds, after many years, were so annoying that the patients applied for relief on this account. In one case it was more than ten years after the injury—Sanson's case. In six cases—Larrey, Kirsch, Wederstrandt, Smith, Fischer, Wedekind—permanent circulatory and trophic disturbances persisted in the arm, not only from associate injury to brachial plexus, but from interference with circulation; in one—Smith's case—gangrene set in, with loss of part of the extremity (fingers, hand and forearm), more than seven months after the patient had recovered from the injury. In the other unoper-

5. If we add the two fatal cases of Reboul and Vallas, reported since the above was written, the mortality is increased to 4:17, or 23 1/2 per cent.

ated cases, with the exception of three (Wattmann's succumbed thirty-two years afterwards, after thirty years of latency; Will's died from secondary hemorrhage three weeks after the injury, and Smith's from gangrene of extremity seven months after), it is only fair to state that the abnormal conditions of the circulation created by this lesion were, with the exception of the annoyances and disturbances previously referred to, fairly well tolerated, and were not incompatible with a long survival and active life. It is well to note, however, that in at least six of these cases the patients were last seen or passed out of the observation of the surgeons who reported them, within a few weeks or months after the injury, while the lesion was still active, and too soon to permit any definite conclusions as to the final outcome of the injury. Bernard, a few weeks; Smith, seven or eight months; Fischer, one year; Letenneur, twenty-one days; Kirsch, two and one-half months; Wedekind, seven months.

#### THE CASES OPERATED ON AND RESULTS.

In 4 only of the 15 cases was an operation resorted to; in 3 cases ligation of the vessel was made imperative by the occurrence of violent secondary hemorrhage following shortly after the injury, and in only 1—my own—was the operation deliberately performed in anticipation of future complications. Three out of these 4 cases permanently recovered except Wattmann's patient, operated in 1810, who died of secondary hemorrhage twenty-three days and thirteen hours after the ligation of the third portion of the subclavian. This case, which is often referred to as a case of traumatic aneurysm of the subclavian artery at its junction with the axillary, is especially interesting to us in this connection, because it illustrates the possible transformation of a passive and benign arterial varix into a rapidly growing and malignant aneurysm of the artery after a long lapse of time. In this case, a gun-shot injury was inflicted in 1809 from which the patient recovered without any great disturbance except cramps in the arm. From 1809 to 1810, thirty-one years, during which the patient was engaged in active military service, he suffered no serious inconvenience. In 1810 an aneurysmal tumor was developed for the first time under the clavicle. This, however, did not enlarge for two years. In 1812 erysipelas and phlebitis set in, and the tumor rapidly grew to threatening proportions. Under these conditions, Wattmann found it necessary to operate. Two ligatures were applied between the scaleni and the tumor, none to the vein; secondary hemorrhage occurred at the point of ligature, which caused the death of the patient. A large varicose sac was found at the postmortem, which communicated with both the artery and vein.

In Rötter's case, in 1892, the signs of arterio-venous aneurysm developed almost immediately after a stab injury; profuse primary bleeding followed. Rötter advised immediate operation, but the patient would not consent until after a nearly fatal secondary hemorrhage occurred on the ninth day at midnight, when Rötter cut down upon the vessels and ligated them outside of the scalenus after resecting the clavicle. The knife had penetrated one inch below the middle of the left clavicle, causing a sharp-edged oblique wound two-thirds of an inch long. After resecting the clavicle and displacing it upward, he was able, by following the track of the wound, to insinuate his fingers behind both vessels as they emerged on the outer side of the scalenus, and by hooking his fingers behind them and dragging them forward was able to control the bleeding until the artery and

vein had been ligated above and below the point of injury. The patient, though much shocked, made a good recovery. The clavicle was sutured back into position. The arm became endo-vascularly pale and cold, but the circulation was finally re-established.

Venel's case is also very interesting:

The patient, aged 23, was stabbed in the right shoulder on May 14, 1894. Wound one-third of an inch below the middle of the clavicle. Profuse hemorrhage and syncope, when bleeding stopped spontaneously. Temperature, about 103, gradually subsiding to normal on the ninth day. Profuse secondary hemorrhage took place at midnight on the ninth or tenth day, while the patient was asleep. He had signs of arterio-venous aneurysm, which were observed for the first time on the tenth day, when septic pneumonia set in. Fearing the repetition of the hemorrhage, which would have been fatal, an operation was performed. Following the track of the wound an incision was made into a pocket situated below the clavicle, but a flood of blood followed which could only be controlled by packing the cavity. While this was being done the third division of the subclavian was exposed and ligated outside of the scalenes, but upon diminishing the pressure and removing the pack in the wound below the clavicle, bleeding followed, which was not controlled until the vein had been exposed and ligated in the sac above and below the injury. A third tributary vein, which continued to bleed freely after the main trunk had been secured, had also to be ligated. Hemoptysis and pyemic pneumonia, with temperature of 104, threatened the life of the patient for several days. Fever ceased only on the twenty-fifth day after the injury, and only after a large phlebotic phlegmon of the arm on the affected side had been opened and a septic venous clot removed. The wound had healed and the patient was discharged two and a half months after the operation in a very satisfactory general condition. The circulation in the arm and its nutrition were affected permanently and very seriously. Eight and a half months after the operation, anesthesia and trophic changes, with a loss of thermic sense, existed, leaving the arm in a state of functional disability.

These four operated cases (including my own fully reported in the first section of this paper) resulted in three recoveries, the only death—Wattmann's—being due to secondary hemorrhage following a ligature applied under very disadvantageous conditions and with the old septic technique. In 2 out of the 3 cured cases serious functional disability followed after the intervention, though in my case, in which partial gangrene of the hand and forearm occurred after operation, there was a coincident paralysis of the arm from injury to the brachial plexus.

#### EFFECTS OF THE ARTERIO-VENOUS LESION OF THE SUBCLAVIAN VESSELS UPON THE CIRCULATION OF THE UPPER LIMB.

The effect of accidental and surgical occlusion of the subclavian vessels upon the circulation of the arm is the cause of much concern in these cases. In analyzing the individual reports of these fifteen arterio-venous injuries or aneurysms we are impressed by the fact that in a large majority the effects of the arterial ischemia and coincident venous obstruction were immediately perceived. Suppression of the brachial and radial pulse are noted in the majority of the cases of which full observations have been recorded; in many, great pallor, lividity of the skin, ecchymoses, coldness of the surface, functional disability, numbness, paresthesia, edema, etc., are recorded as the immediate effects of the injury. In two, extensive interference; in one of these spontaneously—Smith's case; in the other, after the ligation of the artery and lateral suture of the vein—Matas. That the danger of sloughing is not to be lightly considered is well shown in my case, in which, after the ligation of the second division of the artery, followed by torsion of

the proximal end—following Wyeth's suggestion—and after simple lateral suture of the vein purposely done, so as not to interrupt the venous current, complete arterial ischemia followed, causing an extensive dry sphacelation of the several fingers, part of the hand, and forearm. That this was due to complete interference with the arterial and not the venous supply of the limb is proven by the character of the gangrene—dry—and pallor of the skin. This result is important because the ligation was performed with the most aseptic technique and with absorbable kangaroo ligatures, and the wound healed *per primam*. The complete ischemia of the arm can only be accounted for by the torsion which was applied to the proximal end before ligation, which no doubt interfered with the collateral supply from the branches of the thyroid axis, superior intercostal, and possibly the internal mammary. This extra precaution, which was calculated to diminish the risk of secondary hemorrhage, should be avoided, if possible, in future operations.

We have already referred to the tropho-paralytic phenomena which in some cases permanently impaired the usefulness of the arm as a result of circulatory disturbances independently of injury to the brachial plexus—Veiel's case is probably the most notable in this respect. That the danger of sloughing is greater in double—arterio-venous—injuries than after interference with arterial circulation alone is well shown by the comparative statistics of the two classes of injuries. Le Fort, in his learned and careful study of 223 ligations of the subclavian artery for all causes (published in 1867), was able to find only 4 cases in which gangrene occurred, and this was limited chiefly to the fingers—1.7 per cent. These are the cases reported by O'Reilly, White, Blizzard, Terrier, the last complicated by injury to the brachial plexus. Von Bergmann, in 1877, in studying the effects of injury to the subclavian from the same point of view, states that in 90 cases of ligation of the subclavian, gangrene of the fingers occurred in 3 cases—3 1-3 per cent.—and in these this result was attributable largely to the extensive contusion of the skeleton and soft parts about the shoulder girdle. In this respect the risk of gangrene can not compare with the greater frequency of this result in similar ligations of the vessels at the groin.

It is also well established that gangrene is much less frequent after ligations of the third division of the subclavian above the clavicle than after the ligation of the axillary when this is done in the wound.

For instance, Le Fort (*loc. cit.*), in a study of 42 cases of axillary aneurysms, notes 5 cases in which gangrene occurred as a direct result of the traumatism without ligation, and in 6 in which the gangrene followed the ligature applied in the wound at the time of injury.

The gravity of the double—arterio-venous—injuries of the subclavian vessels from this point of view will now be appreciated, when we recall the facts gathered from our statistics that 1 in 11 unoperated cases sloughed—9 + per cent.—and that in 1 of the 4 operated cases this unfortunate result followed—25 per cent.

The extent of the traumatism in the operated cases was, it must be remembered, greater than in the non-operated, since the operation in 3 of the 4 was necessitated by secondary hemorrhage or other grave complicating lesion, whereas secondary hemorrhage occurred in only 1 of the 11 unoperated cases.

To summarize the liability to gangrene of the limb, grossly stated and without reference to special modifying

conditions, it would be as follows for the various lesions: Arterio-venous injuries of both the subclavian artery and vein, including ligations, 13.5 per cent.; after ligation of subclavian artery—third division—1.7 per cent. (Le Fort); or 3 1/3 per cent. (von Bergmann); after obliterative injuries of the axillary, 26.8 per cent. This last percentage relates, however, to cases reported before 1867, and would no doubt be much improved by later statistics; the contrast between the axillary and subclavian injuries is, nevertheless, significant.

(To be continued.)

## REPORT OF A DEATH FROM CHLOROFORM ANESTHESIA,

BEING THE FIRST IN A PRACTICE OF SIXTEEN YEARS, AND INCLUDING NOT LESS THAN TWO THOUSAND CHLOROFORM ANESTHESIAS.

BAYARD HOLMES, B.S., M.D.

Professor of Surgery and Clinical Surgery in the College of Physicians and Surgeons, the Medical Department of the University of Illinois, Etc.

CHICAGO.

It is my unpleasant duty to report the first death from chloroform in my practice, not a very large one to be sure, which began in the Cook County Hospital in 1885. I have not kept a record of the number of anesthetics given for me, but they have certainly not been less than two hundred a year. Chloroform has been uniformly used. Only when a patient insisted on ether has anything but chloroform been given.

It has been my practice to have a skilful person administer the chloroform, even if it necessitated an untried and even inexperienced physician as my first assistant. My anesthetizers have been trained by me to give chloroform on two thicknesses of cheesecloth held over the left index finger or spread on a wire mask. It is administered drop by drop from an ounce bottle with a little notch cut out of the side of the cork. The anesthetizing room is still. The patient is directed to count after the anesthetizer at each full inspiration. Thus confidence and regular breathing and possibly a sort of hypnotic state is secured. This method has been once fully described by Dr. D. H. Galloway.<sup>1</sup> There is rarely any difficulty and almost never any kicking or rolling about on the table. Very rarely has artificial respiration been necessary.

In the case which I am about to report, the anesthetic was given by a physician with whom I had no previous experience and in a hospital where I have not been accustomed to operate. There was no oxygen at hand. My attention was given entirely to the operation. I had no reason to anticipate trouble.

Mrs. McC. was brought to my office for examination on September 28 by Dr. W. M. Watermann. She had all the appearances, on walking into the consultation room, of being 38 years of age and about four and a half months pregnant. I made an examination of her without getting her history. She was medium-sized, well built. The temperature was normal and the pulse 88. She showed evidence of previous pregnancies. The breasts were flabby; there was no marked pigmentation, no blue veins over the breasts. The vagina showed no enlarged veins. The cervix uteri was small, in the median line, hard and high up. It pointed slightly toward the right. The cervix did not seem to move with the abdominal tumor. The tumor had the size, shape and consistency of a pregnant uterus of four and a half

1. JOURNAL A. M. A., May 14, 1898.

or five months. There was one point which seemed to suggest a fetal extremity. This was very absorbing and riveted our attention. No heart sounds could be heard; no distinct placental souffle; no fetal movements felt. The tumor was fixed in the pelvis, did not rotate, and when standing, sitting or reclining had all the appearances of pregnancy.

The patient gave a history of repeated attacks of appendicitis. She insisted that she was not pregnant. She had borne two children, the youngest 2 years old. Five months ago, after a light attack of appendicitis, she noticed a slow, progressive growth of the abdomen. She had menstruated regularly since the last child was born in spite of nursing her. She had none of the subjective symptoms of pregnancy during the time the abdomen was enlarging, which symptoms were very pronounced in her previous pregnancies. Two weeks before she saw me she had an attack of abdominal pain. It was not like her previous attacks of appendicitis, but was deep, long, lasting and accompanied by faintness.

The diagnosis did not seem to us very clear. In spite of the absence of mammary and vaginal signs of pregnancy and the small, hard cervix uteri, and in spite of the absence of all subjective symptoms and the history of continuous menstruation, great importance was given the regular and timely growth of a tumor which was shaped like a uterus and had a feeling like that of an included fetus. It seemed that so regular and timely a tumor must be pregnancy. With the abnormal findings at the cervix we thought of extra-uterine pregnancy. The patient was warned of the possibility of some other form of tumor and urged to have constant medical supervision and a subsequent examination.

On the afternoon of Wednesday, October 2 Dr. Meany, who had the care of the case in the absence of Dr. Watermann, called me up on the telephone and told me our patient had been having more pain, the attacks being very severe. They were still unlike the attacks of appendicitis. She required morphin on Saturday and Monday nights. Her pulse had gone up suddenly to 108, and her temperature was 100.4. She was very sick. I decided to see her at once with Dr. Meany.

At 4 p. m. I was at her home. She was lying on her left side and appeared very sick and pale. She had been vomiting bilious matter for some hours. Her pulse was 120. The abdominal tumor was as large as that of a pregnancy at full term. It was, however, soft and cyst-like. The cervix was still small and hard and the fundus could not be reached. The breasts did not look like those of a pregnant woman. The vagina had no blue veins or other evidence of pregnancy. No fetal heart-beat could be heard.

With presumptive diagnosis of, 1, extra-uterine pregnancy and hemorrhage; 2, tumor arising from the pelvis with twisted pedicle, or 3, pregnancy with some complicating intra-uterine hemorrhage, an operation was proposed and undertaken at the Garfield Park Sanitarium. Dr. J. J. Meany, Dr. Rudolf F. Teschan and Dr. H. J. Stewart assisting. Several other physicians and students were present.

The patient was anesthetized with chloroform in her room and brought to the operating room. She was well scrubbed. She was not profoundly under chloroform during these preparations. The chloroform was pushed and the operation begun. Through a rather large (3-inch) median incision the abdomen was opened. The smooth, black surface of a multicular cyst of the left ovary presented itself. There were no adhesions to be felt.

The trocar quickly emptied the cysts and the tumor was removed. The pedicle was found twisted three times around. It was ligated in two places. The appendix was found very much enlarged, 4 inches long and quite angry looking. It was removed. At no time during the operation was there any anxiety about the patient. No stimulants were used and there was no delay from imperfect anesthesia. The operation had taken less than twenty minutes. On account of the small amount of fluid in the peritoneal cavity, and on account of the slight contamination of the wound edges with the cyst contents, the abdomen was now washed out with warm normal salt solution. This much revived the patient and she resisted and threw her body and legs about. This led the anesthetizer to administer more chloroform and she became quiet again. Suddenly it was noticed that she had stopped breathing. I left the care of the abdomen to an assistant and immediately opened the mouth, drew out the tongue and compressed the root of the tongue forward. The assistants elevated the foot of the table and Dr. Stewart very skilfully performed artificial respiration. This resuscitation was very tardily begun; the heart was beating and the blood became aerated. After washing up and putting on the gloves I closed the abdomen. Artificial respiration was continued. There seemed to be occasional efforts at automatic respirations, but it was necessary to keep up the mechanical breathing. Dressings were applied and the patient removed to her room, placed crosswise of the bed on a stretcher and artificial respiration kept up. Although in better position for this procedure it became less and less effective. She became cyanotic, the heart stopped and she died more than an hour after the first recognition of danger. There was no postmortem.

In considering this case there is only one thing which gives me any comfort. The anesthetizer was a stranger to me and untried. We had never worked together before. The patient had taken the anesthetic well and the operation had been without the slightest incident. The use of the hot normal salt aroused the patient; the anesthetizer gave more chloroform and the patient stopped breathing. For an unknown period no efforts were made to open the pharynx and produce artificial respiration. Some valuable time was lost. The heart continued to beat for three-quarters of an hour after all automatic respiration was suspended. The aeration of the blood was for a long time quite perfect, as shown by the red lips and disappearance of all signs of cyanosis. There is no evidence that the patient died of thrombosis, enzyme poisoning or any other effect of the simple and rapid operation.

When a patient dies of chloroform it is always recognized and properly credited. It seems in every case I have known to have been due to unskilful administration or improper surroundings. When a patient dies of ether narcosis it may be on the table, but it is usually after several days, and it therefore lacks the tragic element so confounding and even terrifying in deaths from chloroform. Too little care and attention is given the anesthetic. A person who gives ether is unfitted to give chloroform. I have extravagantly suggested that when a physician has once given ether he should be tattooed on the hand and never allowed to give chloroform afterward.

---

**Il Lavoro.**—Professor Devoto, of Pavia, Italy, has undertaken the publication of a periodical with this title. It is to be devoted to all questions of a medical and hygienic nature related to the professions and trades, manufactures, etc.

## Clinical Report.

### CASE OF NECROSIS OF BONES OF THE SKULL.\*

W. U. COLE, M.D.

COLUMBUS, OHIO.

The patient is a housewife, aged 34, is a native of Ohio, and is married, but has no children. Seven years ago she came to my office for the first time, suffering from headache and pain in the left hip. She presented a sallow, anemic appearance, and was somewhat emaciated. I also noticed that the anterior and upper frontal regions were unduly prominent, but the skin showed no discoloration. Six months later she called again. Apparently an abscess had formed at the apex of the prominence to the left of the median line, where she complained of severe throbbing pain. The skin over the site of the abscess was a dark-red color, and at one point some signs of ulceration were already visible. I evacuated the abscess under anesthesia. A cheesy tuberculous deposit lined the cavity. At

solution and packed with iodoform gauze. The patient remained in the hospital for two weeks, and the edges of the wound by this time showed signs of the formation of healthy granulations. The wound seemed to make fair progress toward healing for some months. The patient, having learned to dress the wound herself, passed for a time from my notice.

After several months had elapsed, I was called to her residence, and this time found her confined to bed. She complained of severe pain and stiffness of the left hip. The hip was swollen and very tender to the touch. Prior to this time, at each visit, she had complained of pain in the left hip, and occasionally was forced to limp when walking. By this time the patient's weight had decreased very perceptibly. Her temperature was 103.7 F., and her circulation feeble. She was so weak that it was difficult for her to answer questions. On examination of the wound of the forehead, I found that an area of the inner table of the skull was necrosed, and that the visible necrosed portion measured two and one-half inches in both diameters. This area was entirely denuded of flesh, was of dark color, and covered with a purulent discharge. There were numerous openings through the bone into the cranial

its base I noticed a roughened condition of the bone, and found that some small portions of bone could be easily detached with a gouge, which revealed a cavity in the bone extending through the outer table to the diploë.

There was a continuous discharge of greenish pus from the wound for some weeks, and a persistent small sinus. Finally, the wound almost healed, and I lost sight of the patient for some time.

A few months later she called me to her residence, and I found, on examination, that the necrosis had so extended that it now occupied the entire anterior portion of the frontal bone and the diameters of the lesion were about two inches from above downward, and two and one-half inches from side to side. I advised the removal of the necrosed bone, and requested the patient to go to a hospital. Under strict antisepsis, I removed the entire outer table over the necrotic portion. The inner table, though showing no appreciable signs of necrosis, was apparently unnatural in its consistency, somewhat thickened at points, spongy in appearance, and showed other signs of disease. The wound was thoroughly washed with formalin

cavity, from which at each pulsation offensive fluid would exude. She presented the signs of pyemia.

After watching her case for several days, attempting to improve her general condition, and finding little, if any, improvement, I advised the removal of the diseased portion of the inner table. She readily consented to the operation, and on Sept. 11, 1897, with the help of competent assistants, I removed the inner table of the skull to the extent that is perceptible at this time. The operation was performed by the assistance of the Hopkins bonecutting forceps, and after the membrane was wholly relieved of its bony covering I smoothed the edges of the bony circle with a chisel and mallet. After thoroughly cleansing the area of the exposed membrane and the margins of the wound, I covered the exposed surface with iodoform gauze, applied sterilized absorbent cotton, and a bandage for retention of the dressings. The after-treatment consisted in washing the wound twice daily and keeping the denuded membrane thoroughly clean by pouring over the entire surface an antiseptic solution. It was not long before granulations were manifest at points on the margin of the wound. Soon these spots coalesced, showing a healthy granular sur-

\* Presented to the Columbus Academy of Medicine.

face, and after a considerable length of time the wound became covered with a thin, but fairly firm, epithelial layer, with occasional ulcerative patches.

The flattened condition of the forehead indicates the interference with the bone above described, and there are but a few small fragments of the frontal bone remaining. At each pulsation of the heart the contents of the cranial cavity expanding keeps up a constant motion of the covering of the area that is deprived of bone. The patient has gained in bodily weight and at present to all appearances, has medium fair health. She is able to look after her own domestic affairs. She is possessed of all her mental faculties, shows no impairment of any of them, seldom complains of pain, and, in fact, seems to enjoy life fairly well. She takes a great deal of outdoor exercise, which has proven beneficial to her. A few days ago the patient called my attention to a swelling over the upper portion of the right parietal bone, slightly to the right of the apex of the skull. This has been discharging at the upper and outer angle of the wound on the right side through a sinus from the above described lesion. I have made no opening at this point as the natural drainage seems to be sufficient for the present.

Henneke quotes a case of necrosis of the contiguous parts of the frontal and parietal bones and great wing of the sphenoid, that occurred in a patient aged 19, after typhoid fever. At the autopsy, it was found that the middle meningeal artery was blocked by a thrombus. Saviard reports a case in which the entire vault became necrosed subsequent to an injury of the head. Norris gives a case in which considerable portions of the parietal and temporal bones were lost, together with a great part of the frontal and occipital bones. The disease followed upon a fall on the head. A somewhat similar case is recorded by Drummond, where an equally extensive necrosis followed upon a scalp wound. South described the case of a woman, who, in nine years, lost the greater part of both parietals, and some parts of the temporal and occipital bones, from necrosis that was supposed to be of specific origin.

It is important to note that necrosis is not limited by sutures, and it seldom follows their course, but frequently involves the contiguous parts of two or more bones at the same time.

I have a case, a lady, aged 23 years, from whom I have removed about one third of the outer table of the cranium. It was also necessary to remove the lower half of the right tibia on account of osteomyelitis with necrosis, apparently tubercular in origin.

In specimen 1263, in the Museum of the Royal College of Physicians and Surgeons, in London, England, necrosis of the frontal bone began in the inner table, following an abscess of the brain; the primitive cause was said to have been a blow on the head. In specimen 1290, the frontal, parietal and occipital bones were perforated, the cause was said to have been specific. In specimen 1293, the frontal and occipital bones were perforated and three-fourths of the right parietal bone was entirely obliterated. In specimen 1310, all the bones were affected with small perforations and exfoliations, except the occipital. In specimen 1334, large portions of the temporal and frontal bones of the left side were obliterated, and the entire orbit was necrosed from malignant disease. In specimen 1377, the entire cranium was affected. There were perforations of both tables with rough, serrated edges; some of the perforations overreached the diploë, and caused death due to exposure of the membrane. In specimen 1411, a large portion of the frontal and parietal bones of the right side were necrosed and exfoliated; the cause was believed to be specific. In specimen 1424, necrosis from injury, more than half of the frontal bone on the right side was necrosed; the child was 4 years old. The bone was removed six months after with apparent recovery; the patient was thrown from a horse to the pavement. In specimen 1425, the left temporal separated after necrosis; facial paralysis was subsequent and convulsions preceded death. In specimen 1430, male, age 31 years, nearly all of the left parietal bone exfoliated, following a burn; patient lived 15 years; there was a very slight formation of new bone. In specimen 1712, the skull of a child 5 years old, the frontal bone of the right side was perforated; necrosis was probably due to pressure from malignant growths; all of the right orbit

was obliterated except the *orbital* portions of the right malar and superior maxillary were also necrosed, the necrosis was said to have begun in the antrum.

I would conclude that, from observations of the above-named cases and specimens, any of the bones of the skull are liable to necrose, following traumatism or disease.

I would note further that the process of necrosis may originate in either table of the skull, but the outer table is usually attacked first, in this class of cases, as well as those that begin in the inner table, the disease may or may not extend beyond the diploë. It is also worthy of note that, in all of the above-mentioned cases or specimens, the orbits and petrous portions of the temporal bones were unaffected, except the orbits were affected in the two specimens in which the cause was malignant disease.

As to the liability of the functions of the brain becoming impaired after perforation of both tables from necrosis, I am able to find from the statistics that the inferences to be drawn are very indefinite, but I am led to believe that mental disturbances are most common after necrosis of the mastoid process, and are not uncommon after necrosis from specific disease. I would also remark that it would be with great difficulty, if at all possible, for one to make a reasonable approximation of the time that a patient may live after necrosis has begun or even after either large or small perforations of the skull are known to exist, and large or small areas of the meninges are exposed; as in some of the apparently insignificant cases, death may result promptly from exposure of the membrane, meningitis, or pyemia. Again, it is also true that occasional cases, as the first described, may live for an indefinite period, and perhaps die from other causes, with nearly all of one bone removed, and with no natural protection to the membrane from thermal changes, infection, or traumatism, except a very thin epithelial layer which forms over the denuded meninges that is easily wounded and frequently ulcerates.

## The Organization of the Medical Profession.

### III.

#### OBJECTS OF ORGANIZATION.

(Continued from page 177.)

*Collective Investigation.*—There is a great need of some method by which statistics concerning diseases may be collected. For instance, what are the statistics of the whole country as to deaths following operation and deaths without operation in appendicitis? The experience of 100,000 physicians would be of immense value in helping to solve this vexed question. The statistics gathered by a few individuals scattered here and there are practically valueless because they do not cover a sufficient part of the whole. What are the results of glycerinated lymph as compared with the results from the use of dry points? What harmful results have followed the use of the one, and what of the other? What are the facts as regards the curative qualities of diphtheritic antitoxin? What are the facts as regards the prevalence of this or of that disease, or of this or of that complication in certain ailments? There ought to be a way to get these questions answered in such a manner that there could be no possible excuse for guessing, or for depending upon any one's opinion. The scientific facts derived from a collective investigation covering the experience of a very large number of physicians would be invaluable. This has been recognized for years, and such collective work has been attempted in Europe, but with only partial success, owing to lack of proper machinery. If we had a central organization with branches extend-

ing to every village and hamlet in the country, reaching each individual physician, as we must have, we would have machinery that could be utilized for gathering such needed information. With only this hint as to the possibilities in this regard we leave the subject, but ask those interested to think over it further.

*Political Influence.*—Not the least of the objects to be gained by organization is political power. Thus far physicians have had but little political influence, for the simple reason that they have not been united. There is probably no trade, calling or profession in which the individual member wields as much influence as does the physician. No one comes closer to the people than he, and his opinions and influence carry greater weight than do those of any other individual. What is needed is a combination of this influence so that it may be effective when needed. That physicians, when united for political work, are a power, has been proved a dozen times in a dozen different states during the last three or four years. Such a combination to be effective must reach every village, or wherever there is a physician. Politicians will respect us if they know we are united. Otherwise, we shall have as little influence in the future as we have had in the past. The word "political" as used here must be taken in its better meaning.

*Enforcement of Medical Laws.*—Another need for organization is for effective work in enforcing the laws. To get results in the regulation of the practice of medicine it is necessary not only to get the requisite laws, but also to enforce them. To simply put laws on the statute books and do nothing else is only half accomplishing the good that is sought to be obtained. Axiomatic as this may be, the idea has never seemed to be appreciated by those who have been working for legislative enactments and for the regulation of the practice of medicine. Time, energy and money have been spent to get the necessary laws by committees of our state societies and by others, but with this accomplished, nothing more has been done. Laws will not enforce themselves. Of this we may rest assured. We may theorize as long as we please about its being the duty of the prosecuting attorney to attend to this matter, but the fact remains that these politically appointed or elected officers will not do their duty, except in a few instances, because a united profession does not demand it. The individual member of the profession who takes upon himself this duty will generally live to regret it. It is the duty of our state and county societies to take up this work, and until they do we need not expect the laws to be enforced. To effectively accomplish this object it will require coöperative work among the state societies as well as among county societies. It might be suggested here that, in many states at least, the fines collected from infraction of law go to the society which prosecutes and hence the expense of such work would be met by the fines.

*The Business Side.*—While the members of our profession are not supposed to be dominated by commercialism, there must be recognized the necessity for the utilitarian. High ideals, noble motives and self-sacrificing work are the characteristics of the average physician, and his everyday work is proof of this. But while there is a business side to the practice of medicine the average

physician seems to be sadly lacking in business methods, although it is hard to tell why. It is quite probable, however, that it comes from mistaken ideas as to the result of application of business principles to the practice of medicine. It is not our intention here to discuss this all-important question, but only to suggest that a mutual exchange of views in regard to the business aspects of the physician's work would result in much good. A mutual understanding as to fees, collections, etc., among physicians living in a neighborhood could not but result, in many instances, in a better provided home for the doctor's family. But here let it be said that there must be no forcing in this matter, as has been attempted in a few instances by societies. If a voluntary mutual agreement can not be carried out, there must be no penalty attached for its infraction. If one man persists in placing a low price on his services, in opposition to the wish and practice of the other physicians in his neighborhood, it will not do to turn him out of the society or fine him for this. Such a one will, in time, learn that no man ever made a reputation by placing his services lower than those of his fellows, and that he who places a low estimate on his abilities will find that his patients will generally judge him by his own standard. If a physician makes it a point to court the patronage of deadbeats against the protests of his fellow-practitioners, it will not be good policy to fine or totally ostracize him. Moral suasion, backed by an intelligently organized profession, will do much good in these cases.

*Club Practice.*—This is growing in this country slowly but surely. It has become a curse to the medical profession in many parts of the old world. When it is almost too late, the profession is organizing over there to fight club practice, but it is a hard fight, because the system has become established. This same fight will have to be undertaken in this country, for club practice in its worst form is growing rapidly. Here it is not only the true club practice, but it is worse. The original idea was a banding together of the poor who could pay but little, and by this banding together were able to employ a physician and pay him a fair amount for his services. There is no objection to this. But this principle is extending now to organizations gotten up by individuals for personal profit, the object being to buy physicians' services at wholesale and sell them at retail, not to the poor and needy, but to the well-to-do and to those who are able to pay. There is only one way to meet this organized effort to degrade our profession, and that is by organized resistance. We wish we could impress on every physician the fact that this thing is surely spreading, for if it could be realized in time, it could be met. We predict that in less than five years the "battle of the clubs" will be on in this country and that it will be much more serious than that which our friends across the water are waging to-day if it is not recognized in time.

(To be continued.)

## THE RESPONSIBILITY OF CZOLGOSZ

The literature of the medico-psychologic aspects of the Czolgosz case appears likely to be somewhat voluminous. Besides the quasi-official statements of Drs. MacDonald and Spitzka, there have lately appeared other articles discussing the assassin's mental condition, taking somewhat different views, at least by implication. Talbot's article,<sup>1</sup> noticed in *THE JOURNAL* of January 4, infers that the proof of his sanity was hardly of a satisfactory and logical character, and still more recently Hughes<sup>2</sup> takes practically the same view. The latter regrets the precipitancy of the trial and execution, and the imperatively hasty autopsy. "Czolgosz's egotism," he says, "was unbounded and morbid. His mind was evidently weak, and he appeared as a mental tool of wrong teaching, environment and influence. Unbounded egoism, projecting self into unnatural spheres and phases of action out of normal harmony with environment, is a characteristic of insanity, and it was sufficiently prominent in the case of this murderer, to have justified more extensive inquiry into the mental makeup of this strange assassin." To the average man it makes very little difference whether this malefactor was abnormal or not; that he was sane enough for execution, will be his verdict. It is a matter, however, of some interest to psychologically minded criminologists and anthropologists, and we need not pass by the fact that some of them are not satisfied with the data obtained. It might have been better had his brain been given for fuller study, but is there a valid reason for questioning the conclusions drawn from such facts as we have? Have we good grounds for considering the act as necessarily due to the morbid egotism of a degenerate, incapable of taking normal views of the nature of his act? This seems to us the implication in Hughes' paper and the basis of his regrets that further opportunities were not given for autemortem study and post-mortem pathologic examination.

The facts are these: Czolgosz was an imperfectly educated young man of non-American antecedents. His associations and training had been those of a laboring man; but he had apparently been only irregularly employed, and his physical condition was not, according to the postmortem report of Spitzka, such as would indicate recent hard labor. He had discarded all religious

beliefs and had thoroughly imbibed the principles of the gospel of discontent preached by certain labor agitators and politicians of the present day. His use of an alias is also worthy of note. He attended anarchistic meetings, and claimed to be a disciple of Emma Goldman. All this is consistent with a certain sort of sanity and full responsibility, unless we believe in an organized and intelligent criminal lunacy with its ramifications throughout the civilized world. Physically he was normally developed, and appears to have had no more than usual of the ordinary stigmata of degeneracy; his brain, aside from a possibly exceptional symmetry, was macroscopically that of an average individual. The abnormal egotism claimed is not apparent to us in his history or conduct after his crime; these seem rather to be perfectly consistent with the presumption that he acted solely as an anarchist of the extreme modern type, whether as an appointed agent or independently. Indeed, from all the circumstances, from his lack of ostensible means of support and his mysterious journeys to Cleveland and Chicago, it seems to us that he was entirely alone in the planning of his crime is the less probable supposition. His disclaimer of accomplices and the manner in which he met his fate are perfectly consistent with this theory. Nor would the fact that he had no formal support make any essential difference; his act and conduct were consistent with his professed principles, and while it might be pleasanter to believe that such a crime as his could be committed only by a lunatic, reason and history prove the contrary. In this case there were none of the definite marks of degeneracy, nor is there in the crime anything that is psychologically inconsistent with the possibilities of a mediocre but not abnormal mental organization under certain vicious conditions of environment.

We need not admit any genuine altruistic element in Czolgosz's motive; the altruism of the murderous anarchist is that of the French Reign of Terror or the Paris Commune—a bloodthirsty working-out of the evil passions of hate and envy. It is the stirring up and sowing of these that is the trade of the modern agitators, and they find in such as Czolgosz a fruitful soil for the seed. Traditions of tyranny and disappointed expectations of wealth and license make many of the ignorant foreigners of certain races in this country ready disciples of anarchy. Collectively they are a social problem, but their individual psychologic interest must depend not so much on their anarchistic tendencies and acts as on the special evidences of abnormality that they individually present. These seem to have been absent in Czolgosz; he was not an original paranoiac of the higher grade, like Guiteau, or one closely bordering on imbecility, like Prendergast; he was, rather, from all the evidences, of average normal mentality but misled by the more vicious social tendencies of the present time. The possibility of his being a degenerate, or mentally abnormal, appears to us to be a purely *a priori* assumption not sufficiently justified by the facts.

## ARTIFICIAL SUSCEPTIBILITY TOWARD THE BACILLUS OF SOFT CHANCRE.

In 1889 Ducrey reported that in successive chancreoid ulcerations produced by inoculations of human beings with the chancreoid pus there occurs constantly the same bacillus. Since then the etiologic relationship of this bacillus has been confirmed by Krefling, Colombini and others. The bacillus has been cultivated upon various media, especially serum-agar, and typical ulcerations have been produced in human beings by inoculations of pure cultures of the bacillus. Recently Himmel<sup>1</sup> has shown that coagulated blood of guinea-pigs, allowed to stand for a time or heated to 55 C. for half an hour, constitutes an excellent nutrient medium for the bacillus of soft chancre. He recommends cultures upon this medium as an auxiliary method of differential diagnosis in doubtful clinical cases. As was the case with previous investigators, Himmel also failed to obtain positive results by injections into animals of pure cultures of the bacillus. In guinea-pigs the bacilli, injected subcutaneously under the dura, or intraperitoneally, are rapidly destroyed by phagocytosis. Krefling and others have described in human ulcerations and other lesions the presence of bacilli in large numbers within pus cells, and Himmel suggests that in this circumstance lies the probable explanation why general infection of the bacillus of Ducrey does not occur.

Himmel tried various methods for securing on the one hand a diminished resistance of the guinea-pigs and on the other hand an increased virulence of the bacillus, but without any satisfactory results until he used injections into the abdominal cavity of four drops of lactic acid diluted with one cubic centimeter of physiologic salt solution followed by injection of the bacillus. Phagocytosis now did not occur and the animals so treated died, pure cultures of the bacilli being obtained from the peritoneal fluid. Lactic acid by its so-called negative chemotaxis prevented phagocytosis of the bacilli. By repeating these experiments, diminishing each time the quantity of lactic acid, he finally obtained bacillary cultures of sufficient virulence to kill guinea-pigs without the use of lactic acid.

He obtained similar results by another method which though more complicated and obscure in its mechanism is equally if not more interesting, namely, by first injecting anti-alexin. Anti-alexin is produced by injecting one animal with the serum of an animal of another species. The serum of the injected animal materially now reduces the bacterial action of the blood of the animal furnishing the serum injected either by directly neutralizing its alexin (complement) as urged by Wassermann, or by preventing leucocytosis and phagocytosis (Besredka). Preliminary injection of anti-alexin serum, according to Himmel, so reduces the resistance of guinea-pigs to the bacillus of soft chancre that they fall victims to otherwise harmless doses, and the bacillus acquires an increasing virulence when passed

through several animals so treated. By these clever methods an originally harmless organism was rendered virulent for otherwise insusceptible animals. The experiments also throw light upon the mechanism of immunity. Whether the importance assigned by Himmel to the phagocytic leucocytes should be accepted unreservedly is perhaps questionable; it may well be that the facts observed are equally explainable from other points of view.

## AMEBIC DYSENTERY IN CHILDREN.

While cases of amebic dysentery have been observed in considerable numbers in various parts of the United States, the infrequency of the disease in children accounts for the very limited data possessed regarding the disease in early life. In 1897 Holt wrote that it was then impossible to say what part the ameba coli played in the colitis of infancy and early life, and in 1898 Rotch spoke briefly of the disease as rare in children and of a very unfavorable prognosis. In a series of 35 cases reported by Harris in 1898, only 4 were under 10 years of age.

In a recent contribution to the subject of amebic dysentery in children, Samuel Amberg<sup>1</sup> has added very much to the clinical knowledge of the disease. Besides the four cases of Harris, he refers to two others which have been observed in the United States in which the ameba was demonstrated in the feces, and he adds five cases observed by himself, occurring in the service of Osler. His cases were from two and three-quarters to five years of age. Following the classification of Harris, four of the cases belong in the group of the very mild form; there was little effect upon the appetite and general health and the stools varied from two to six in twenty-four hours, with no fever or acceleration of pulse worth mentioning. Harris had referred to this form as the usual one in children, and the small amount of discomfort experienced by the children is a striking feature. Amberg's fifth case belongs among those of moderate severity. In two cases prolapsus recti was observed. No hepatic complications were present in any case, and amebic abscess of the liver seems to be very rare in children as compared with adults. Amberg was able to find but twelve cases in the literature where abscess of the liver followed dysentery in children, and in only two of these were amebae demonstrated. The symptoms correspond quite closely to those in adults. The feces may be formed with bloody, mucoid masses on the surface, or there may be loose passages containing more or less blood and fragments of mucus. The diagnosis was always based upon the finding of motile amebae containing red blood corpuscles in the feces.

Charcot-Leyden crystals in feces have often been referred to by writers upon amebic dysentery, and their presence in the feces of persons suffering from helminthiasis is well known. They were present in four of Amberg's cases, and with them were always associated

1. Ann. de l'Institut Pasteur, 1901, xv, 928-940.

1. Bulletin of the Johns Hopkins Hospital, 1901, xii, 355-363.

eosinophile cells and free eosinophile granules in varying abundance. Because of the inconstancy of the picture of the feces, Amberg is unable to draw a conclusion regarding the relation between the numbers of amebæ, crystals and eosinophile cells. In any case, Charcot-Leyden crystals in the passages of a child should always excite a suspicion of amebic dysentery, and this is of especial importance as the amebæ may be found only after repeated examinations. The significance of the eosinophile cells must be determined by further study. Now that attention has been called to the subject by a series of carefully studied cases, we may expect further observations upon similar cases in the near future. The accurate diagnosis is of much importance from the side of treatment, as injections of quinin solutions appear to be most efficient in combating this variety of dysentery.

#### AUTO NEPHROTONINS IN OPERATIONS UPON THE KIDNEYS.

In view of the frequency with which the kidney and connected structures are subjected to surgical operations of various kinds it may not be without interest to recall certain results obtained from experimental operations in this field. Castaigne and Rathery<sup>1</sup> find that in unilateral nephrectomy of rabbits the mortality is very small—in 12 cases only one death, and that was from post-operative peritonitis. On the other hand, unilateral ligation of the renal artery, of the ureter, or of the entire mass of the pedicle of the kidney is followed by a much greater mortality, namely, 34.8 per 100. In these cases death could not be ascribed to any other causes than such as were directly connected with or dependent upon the ligatures, and it would appear as if the kidney, compromised by the tying of its vessels or of its ureter, or both, constitutes a source of danger for the organism. The observation that in rabbits certain conservative operations are more dangerous than unilateral nephrectomy (the remaining kidney being healthy) may or may not be applicable to man; the facts observed are certainly worthy of consideration.

In looking further for the causes of the increased death rate after ligation as compared with unilateral nephrectomy, Castaigne and Rathery studied the microscopic appearances of remaining or opposite kidneys in these two sets of cases. In unilateral nephrectomy the remaining kidney showed no changes whatsoever of a degenerative type. After ligation of artery, ureter, or entire pedicle, marked degenerative changes are present in the epithelium of the convoluted tubules of the opposite kidney; the glomeruli also show well-marked changes. Such alterations, more commonly present in spots than in a diffuse manner, seem most pronounced after ligation of the entire pedicle.

Now, what is the mechanism of this lesion? Because it is absent in unilateral nephrectomy it can not be attributed to defective elimination of ordinary urinary

constituents. It lies very near at hand to trace the lesions in the opposite kidney to the toxic action of the products of disintegration of the kidney whose vessels or ureter have been tied. In other words, may it not concern an auto-nephrotoxin similar in its general actions to cytotoxins of other kinds. The blood of animals whose ureters have been tied has been reported toxic for the renal cells of other animals. The substances that develop under these conditions may be autotoxic as well as heterotoxic. Perchance certain renal disturbances now described as the result of reno-renal reflex nervous influences or as sympathetic nephritis are the outcome rather of auto-nephrotoxins.

#### HAHNEMANNISM EXTRAORDINARY.

A journal,<sup>1</sup> representing what we take to be a very small fraction of extreme Hahnemannians, makes the following astounding assertion in its editorial columns: "The use of antitoxin and the crude vaccine virus belongs to the domain of material things and they should have no place as therapeutic agents in the armamentarium of the homeopath." This is certainly a very short step from Eddyism pure and simple, lacking only the sanctimonious pretensions of that pseudo-Christian cult.

#### A NUCLEUS OF STATE RECIPROCITY IN LICENSING.

Representatives of the State Medical Examining and Registration Boards of the States of Indiana, Michigan, Illinois and Wisconsin met in Chicago last week and organized under the title of the Confederation of Members of Reciprocating State Medical Examining and Licensing Boards. The objects of the organization were embodied in the report of the committee to draft a policy, which was adopted and which is given elsewhere in this issue. The states formally endorsing this report will be guided by it, but will arrange an itemized standard of preliminary qualifications and medical course that will be required. This seems like a seriously conceived step toward reciprocity of licensure and we hope it will prove to be in the right direction. It appears from the report that there is left a large discretion with the several Boards, which is, we believe, as it should be. Limitations by ironclad rules, making it necessary to admit all cases alike without exception, would be a mistake and not justified by any needs. It is assumed, of course, that each Board will keep close watch of each other's methods, and the plan of recognizing each other's certificates of not less than one year's standing will help to prevent error being committed. (See pages 260 and 261.)

#### THE BARRING OF CONSUMPTIVE HEALTH-SEEKERS.

In view of the recent proposed action in California, Colorado and elsewhere against the admission of consumptive health-seekers, a lay paper suggests that before New Mexico and Arizona are ever admitted to statehood, there should be a pledge required that at no time shall the consumptive be excluded from them. This

1. *Compt. rend. de Soc. Biol.*, 1901, III, 1150-1154.

1. The Hahnemann Advocate, January.

is a matter of some interest to the medical profession as well as to the victims of tuberculosis. There is a serious moral question involved in the question whether a state has a right to shut off its climatic advantages from those who most need them, and the impropriety of such a course in states that have largely been built up by health-seekers would be obvious. In the present prevailing panic in regard to tuberculosis there is a possibility of such measures being enacted. In California it has been gravely proposed to exile consumptives to the exclusively desert regions, and boards of health are talking about isolating them like cases of smallpox or leprosy. If regulations like these should be enacted they would probably pass sooner or later into innocuous desuetude, but while they stand on the statute books they will afford opportunities for annoyance and oppression that could be ignorantly or maliciously utilized. It might perhaps be a good thing to have the legislators undergo a tuberculin test, when such laws come before them, so as to determine how many of themselves they wish to legislate into compulsory retirement.

#### FOREIGN CURRENT MEDICAL LITERATURE.

In this issue of *THE JOURNAL* we commence the listing of titles of original articles in foreign literature, beginning with the year 1902, on a plan practically identical with that we are using for American publications. Purely casuistic articles and clinical reports on common disorders, and mere abstracts or reproductions of articles published elsewhere, will be omitted from the lists. Of course, not every foreign publication will be listed, but it is the intention to include so far as possible the leading or representative ones in all languages. The advantages of this to our readers will be obvious—it will afford them to a great extent a corresponding outlook on foreign medical literature to that heretofore only given of that of our own country. The abstracts of leading articles from foreign publications will appear as heretofore, but will be presented in the same manner as those from American periodicals. In this issue the British journals alone have been utilized, the continental literature for January not having arrived in time. This course has been adopted at the suggestion and request of a number of prominent physicians, close students of medical literature who find our weekly exhibit of the current publications of decided advantage in their work, and, therefore, wish to have it extended to contributions from foreign sources also. It is believed that the addition will be generally welcome to the readers of *THE JOURNAL*. The republication of titles and index will follow the same rule, so that at the end of each volume there will be a cosmopolitan résumé of the medical literature of the current half-year, thus making it practically an index medicus for the period.

#### MEMBRANOUS INFLAMMATIONS OF MUCOUS SURFACES CAUSED BY THE PNEUMOCOCCUS.

Cary and Lyon<sup>1</sup> describe a remarkable case of acute lobar pneumonia in a boy of eleven years during which a profuse membranous exudation appeared upon nearly all the mucous surfaces open to inspection. There was

also clinical and other evidence that the fibrinous inflammation involved also the pleura and the gastro-intestinal tract. A protracted and severe course terminated by lysis, and the case ended in recovery. The exudation was observed upon the mucous membranes of the mouth, tongue, throat, nose, eyes, glans penis and anus. Pure cultures of the pneumococcus were obtained from the eyes and nose, mixed cultures of pneumococcus and the golden pus coccus from the mouth and sputum. There seems to be little doubt that the pneumococcus was the essential factor in this remarkably widespread process. While pneumococcic inflammation of serous membranes are only too frequent, fibrinous exudations upon mucous membranes due to the pneumococcus seem rare. Cary and Lyon, in reviewing the cases, divide them into those occurring in connection with pneumonia and those occurring as a purely local process. All the reliable cases date back but a few years, and it is only recently that the pneumococcus has come to be recognized as capable of inducing fibrinous exudations upon various mucous membranes. Membranous inflammations of mucous surfaces caused by the diphtheria bacillus and by streptococci are not distinguishable from the pneumococcic except by bacteriologic methods. Most of the pneumococcic cases arise in childhood and early adult life. As a rule they have been mild, ending in recovery, but refractory instances occur. Almost any mucous membrane may be involved and undoubtedly the infection may be transplanted in various ways: by direct contact as, for instance, with the fingers, which in Lyon and Cary's cases were blood-stained from picking at nose and lips; by the circulating blood which may contain pneumococci in lobar pneumonia; and by swallowing of sputum and exudate. Local germicidal agents usually give good results, but failed entirely in the case that forms the text for Lyon and Cary's paper.

#### INCREASE OF PHYSICIANS IN GERMANY.

The number of physicians in Germany is steadily on the increase, nearly 3 per cent. having been added during the past year, though this is somewhat under the figures of the years 1894 to 1899. In Prussia the increase was over 3 per cent. The increase can be better shown by the comparison of the relative additions to the profession and to the general population since 1895. From this it appears that while population has increased in the German empire 7.8 per cent. the number of physicians has increased 18.6 per cent., or over double, and in some sections three or four times as much. The proportion of physicians to the general population is given as 1 to 2000 for the German Empire as a whole, but in the cities it is much higher, ranging from 1 to 489 in Kiel to 1 to 1918 in Barmen. The university towns have naturally the largest proportion, and those where industrial operations are chiefly or alone carried on the least. Our German confrères, it will be seen, have to some extent the same problem of excess of physicians to deal with as we have here; in fact, it seems to be a world problem, and how it is to be worked out is one of the interesting questions of the social economics of the day. Just at present the conditions do not seem to meet our professional ideals of supply and demand in Germany

1. *Trans. Assoc. Americ. Physicians*, 1901, xvi, 379-392.

## CALIFORNIA

**Personal.** Dr. John M. Henderson, who has been on the staff of the Rio Grande Hospital, Saltillo, has been appointed surgical lieutenant colonel, Rio Grande Railway Company.

Dr. A. T. Steele, of Charleston, has been confined to his bed since August 4. While attending a case of labor he received a stroke of paralysis.

**Railway Emergency Case.**—The consulting surgeon of the Chicago and Alton Railroad has designed an emergency medical and surgical case which is to be placed on every passenger train on the road.

**Journals Refuse Irregular Advertisements.**—Two of the daily papers of Charleston have refused to take the "ads" of traveling quacks who make towns for a one-day stand.

**Macomb Hospital.**—The deed to the land on which is to be built the new hospital of the Sisters of St. Francis, at Macomb, has been recorded, and it is expected that the hospital will be in operation before the close of the year.

**Zion Bars Doctor.**—Dr. E. F. Gavin, Waukegan, local surgeon of the Chicago and Northwestern Railway, was directed to go to Zion City to attend a youth injured by a fall from a train, but was not allowed to enter the city, and in fact, was ordered out of Zion!

**Smallpox.**—The school in the South Walnut Grove district, Independence township, has been closed on account of the prevalence of the disease.—At Kansas, 2 additional cases have developed.—Springfield had 32 cases and suspects under care, January 14.—At Decatur a new nidus was discovered, January 14, and 12 patients were removed to the isolation hospital.—Elkhorn has 6 cases.—Cases are reported from Carlinville, Breckenridge, Cotton Hill, Freeport and Peoria.—Smallpox is present in Coles and Clark counties. Several cases have occurred in Charleston and Rardin and a few in the country districts. One death has been reported at Westfield.

#### Chicago.

**Scarlet Fever Increases.**—Scarlet fever shows an increasing prevalence. The disease increased 35 per cent. during the first 18 days of January over the last 18 days of December, while diphtheria has increased less than 10 per cent. in the same period. The figures of mortality from the two diseases are even more striking—34 per cent. decrease in the deaths from diphtheria and 25 per cent. increase in the number of scarlet fever deaths.

**Mortality.**—Exactly the same number of deaths—516—were recorded last week as for the week before. This number is seven more than for the corresponding week of January, 1901, but on the basis of population the annual rate last week is about 2 per cent. less than that of a year ago, the respective rates being 14.78 and 15.09 per 1000. The continued low mortality is a source of surprise to the officials of the Health Department in view of what are usually accounted as extremely unfavorable and unseasonable weather conditions.

**Local Tuberculosis Pavilion Needed.**—At the meeting of the Chicago Medical Society, January 8, the following resolution was unanimously adopted:

*Resolved,* That the Chicago Medical Society petitions the Honorable Board of Commissioners of Cook County to erect a pavilion for tuberculous patients who are gravely ill in the city of Chicago, within practical distance of the center, so as to command the attendance of an efficient medical and surgical staff; and it further petitions that the modern plan of treatment of tuberculous patients who offer hope of recovery be instituted in small cottages located at some suitable place in Cook County.

**Smallpox.**—There have been but 18 cases this month and only 30 since Aug. 12, 1901. Some apprehension had been felt lest the hundreds of thousands of visitors during the shopping season should spread the contagion broadcast, but Chief Medical Inspector Spalding's careful search reveals only 5 out of the 18 cases the origin of which could not be traced directly to imported cases. As has been the uniform rule during the thirty-four months of this epidemic, not one of these had ever been vaccinated. Although the contagion has been frequently introduced and thousands have been exposed, the disease picks out with unerring accuracy only those "never vaccinated."

#### INDIANA.

**Epidemic Diseases.**—Richmond is said to have 176 cases of measles.—Scarlet fever is reported to be epidemic in Putnam County.—Diphtheria is still prevalent at North Judson.

**Hospital for Consumptives.**—The State Board of Health states in its annual report that 4000 deaths occur annually in the state and that there are at least 25,000 sufferers from the disease, probably 1200 of whom must be cared for at public expense. The board therefore recommends the erection of a state hospital.

**Mortality.**—Reports to the State Board of Health show there were 2842 deaths in the state in December, 1901, an annual rate of 13.3 in 1000. In the preceding month there were 2402 deaths, and in December, 1900, there were 2880. By important ages the deaths were as follows: Under 1 year, 380,

or 14.8 per cent. of the total number; 1 to 4 years of age 151, or 5.6 per cent.; 65 or over, 765, or 28.7 per cent. From important causes the deaths were: pneumonia, 380; tuberculosis, 359; typhoid fever, 86; diphtheria, 53; scarlet fever, 18; measles, 3; whooping cough, 11; cerebrospinal meningitis, 22; influenza, 25; puerperal fever, 14; cancer, 81; violence, 148. The urban death rate was 15.4 per 1000, and the rural 12.2 per 1000.

**Morbidity.**—The cases of smallpox reported numbered 465, in the following counties: Vanderburg, 40; Kosciusko, 26; Tippecanoe, 41; White, 1; Union, 13; Lawrence, 1; Spencer, 31; Vigo, 1; Owen, 3; Scott, 12; Pike, 1; Marshall, 3; Switzerland, 1; Randolph, 3; Dearborn, 9; Warren, 1; Knox, 4; Wabash, 19; Warlick, 41; Shelby, 12; Jefferson, 80; Marion, 12; Wayne, 40; Davis, 41; Decatur, 3; Madison, 2; Perry, 20, and Delaware, 4. One death occurred in Warlick County and one in Tippecanoe. Reports from county health officers show that the following diseases prevailed in the order given: Tonsillitis, bronchitis, influenza, rheumatism, pneumonia, typhoid fever, intermittent fever, pleuritis, scarlet fever, diphtheria, diarrheal troubles, erysipelas, inflammation of the bowels, measles, dysentery, puerperal fever, whooping cough, cerebrospinal meningitis, cholera morbus and cholera infantum.

#### KANSAS.

**Damages Against Doctor.**—In the case of G. W. Coffee against Dr. William C. Bower, Lebanon, for \$5000 damages resulting from malpractice, the jury assessed the damages at \$1200. Dr. Bowers has moved for a new trial.

**Penalty of Non-Registration.**—The County Board of Wyandotte County has declined to pay bills of eight physicians for services rendered at autopsies because they had not registered. Unregistered practitioners have no legal recourse.

**Centenarian Practitioner.**—Dr. John P. Wood, Coffeyville, passed the century mark, January 4. He has been in practice for 78 years and is undoubtedly the oldest practicing physician in America, if not in the world. He still makes his circle of calls on patients, but for the last few years has declined to take night calls.

**Smallpox.**—An Ellinwood anti-vaccinationist practitioner has smallpox.—Cloud County has an epidemic, with 20 cases at present.—Several cases are reported near Hutchinson and one school has been closed.—A number of cases are reported east of Belleville, and several district schools have been closed.—In Linn County a camp of woodchoppers is isolated on account of smallpox.—Topeka has 6 cases.—Fort Scott has 4 cases in its isolation hospital.

#### MARYLAND.

**Tetanus Deaths.**—In 1901 there were 32 deaths in Baltimore from tetanus, 26 being in infants under 21 days old; 12 occurred in one ward. In no case did it follow vaccination.

**Baltimore Deaths.**—The number of deaths for the week ended January 18, was 207; males 111, females 96; white 156, colored 51. The chief causes were pneumonia 26, consumption 22, diphtheria 6, typhoid fever 4, and scarlet fever 2.

**Feeble-Minded School Report.**—The seventh biennial report of the Maryland Asylum and School for the Feeble-Minded shows that there are 95 inmates. A new cottage has been erected with a capacity for 75 additional children and a new school building completed at a cost of \$42,888.

**Dr. Wiener's Anniversary.**—Dr. Morris Wiener celebrated his ninety-first birthday at Baltimore, January 15. He was born in Vienna and educated at the medical school there. He first settled in New Orleans, coming to Baltimore in 1848. He is the author of several dramas and was an editor of the *German Correspondent* here for a number of years.

**Report of State Hospital.**—The one-hundred and fourth annual report of the Maryland Hospital for the Insane shows that there are now 530 patients there: 286 males and 244 females. Of these, 22 are private and 508 public patients. During the year 16 were discharged as recovered, 10 as improved, 13 as unimproved, and 32 died. Attention is called to the large number of chronic cases which present no hopes of recovery and but little improvement.

**Quarter-Centennial of Johns Hopkins University.**—Elaborate preparations are being made for the celebration of the quarter-centennial of Johns Hopkins University on February 21 and 22. Dr. D. C. Gilman, president emeritus, will deliver the commemorative address February 21, followed by an official reception to the delegates. In the evening there

will be a general reception in McCoy Hall. President Rensen will deliver his inaugural address on the next afternoon at three, and will outline the future policy of the University. The annual meeting and banquet of the alumni will be held the same evening, and Hopkins graduates are expected from all parts of the United States.

**Re election of Senator Gorman.** The legislature of Maryland has elected Arthur P. Gorman as Senator from Maryland, to take effect March 1, 1903. The members of the medical profession may congratulate themselves on Mr. Gorman's re-election, for no member of that body has been a better friend to them. The members of the regular profession who have had to deal with medical matters pending in the Senate will remember Senator Gorman's universal courteousness and attention to their interests. The first Pan American Medical Congress owed its tangible existence and success to the efforts of Mr. Gorman, who succeeded in re-introducing and finally securing the appropriation of \$10,000 for this Congress after its defeat by Mr. Holman in the House of Representatives. His subsequent interest and efforts in behalf of the medical profession in defeating the obnoxious anti vivisection bill is one of the last but not least services to the profession. All proper medical legislation before Congress will find a friend and champion in Senator Gorman.

#### MASSACHUSETTS.

**Decoration for Dr. Hogner.** King Oscar of Sweden has shown his appreciation of the attainments of Dr. Richard Hogner, Boston, by making him a Knight of the Order of Vasa.

**Refuse Contract Work.** The physicians of Cape Ann have banded together and have voted to take no more contract work from fraternal societies. Let us hope that the members will hold to their high standard and that past history of rate-cutting will not be repeated.

**Emergency Station.** The new city hospital relief station on Haymarket Square, Boston, is almost ready, and will be opened about February 1. It is on the site of the old Boston and Maine terminus. The hospital has a capacity of 25 beds. It will have 3 ambulances in constant service. The building is three stories in height, has a frontage of 71 feet, and is 120 feet in depth.

**Massachusetts State Sanatorium for Consumptives.**—The trustees of this institution have sent out a circular to physicians, calling attention to the fact that in no sense is the sanatorium to be considered a "consumptives' home," but rather an institution where the patients with slight disease can be sent with a hope of cure, or of such amelioration of symptoms that they may become wage-earners again. It is an educational institution where the patients are taught the simple but important laws of hygienic living, and as such is a factor in the foundation of preventive medicine. Cases suitable for treatment are those in which there may be signs of incipient disease only. Less favorable cases, but still suitable for treatment, are those showing only slight changes of temperature; some impairment of general strength, with one or both apices showing dulness, with râles, sometimes even with cavity formation, if a dry condition seems to prevail; absence of all symptoms showing laryngeal and marked digestive disturbance. The attending physicians of the Sanatorium urge the members of the profession to visit the institution, that they may observe the methods employed there. A single visit will be far more convincing than any other method of information. The superintendent, Dr. Walter J. Marchey, will always be glad to welcome members of the profession and explain the methods employed at the Sanatorium.

#### MISSOURI.

**New Hospital Completed.** The new hospital of the Confederate home at Higginsville has been completed at a cost of \$15,000. At present the home has 150 inmates, the largest number in the history of the institution.

**Dr. Vilray P. Blair,** late surgeon in the African Royal Mail S. S. Co., has returned to St. Louis much improved in health. He has had interesting experiences on the West Coast of Africa, which were the subject of a paper he recently presented to the City Hospital Society.

**Dr. Carson,** president of the St. Louis Medical Society, has appointed his rival in the presidential race, Dr. King, chairman of one of the important committees, and the ex-president, Dr. Newman, to the chairmanship of another. The society is harmonious and largely attended.

**Medical Director Appointed.**—Dr. Leonidas H. Laidley, St. Louis, has been appointed Medical Director of the Louisiana

Purchase Exposition. His duties begin at once in the oversight of the workmen and the construction of the temporary hospital. There are many applications for assistant positions.

**Tetanus Antitoxin Inquiry.**—The Board of Health of St. Louis is scheduled for a thorough investigation, which follows closely upon the antitoxin inquiry recently closed. The mayor seems determined that each city department shall prove its efficiency, and when the verdict in the antitoxin case is rendered, there will be further search into the efficiency of each branch of the health service. Suits have been entered against the city by the parents of some of the children who died from tetanus, and other suits will undoubtedly follow.

#### NEW YORK.

**Gift to Academy.** Mr. Charles T. Harn has presented \$5000 to the Rochester Academy of Medicine, to be used to further medical research.

**Change of Name.**—The Women and Children's Hospital Association of Syracuse has changed its name and will hereafter be known as the Syracuse Hospital for Women and Children.

#### New York City.

**Norwegian Hospital, Brooklyn,** has received for several years an anonymous annual donation of \$3000. It is now learned that the benefactor was Mr. Clark, of spool cotton fame, who has bequeathed the sum of \$64,000 in trust to the hospital, with the provision that the interest be applied for the relief of the sick and the needy through the agency of the Norwegian Lutheran Deaconesses' Home and Hospital in Brooklyn.

**Scarlet Fever in Hebrew Asylum.**—As a result of an outbreak of scarlet fever in the Hebrew Orphan Asylum at 138th Street, several hundred children are quarantined in that institution, and many children in Grammar School No. 48 have been exposed to the disease. Many of the asylum children attend this school, but so far no cases of scarlet fever occurring among the other children in that school have been traced to the asylum.

**Manhattan Maternity.**—It is announced that very shortly the poor of the east side are to be provided with a new hospital, to be known as the Manhattan Maternity and Dispensary. It is to be built in East 60th Street, near First Avenue. Moses Taylor, Henry L. Taylor, Cornelius Vanderbilt, William Sloane and other prominent citizens are especially interested in the work. It is rumored, though not definitely stated, that the hospital is largely the gift of Henry L. Taylor.

**The New Movement in the Health Department.**—Dr. Lederle has commenced his administration of the health affairs of New York by innovations which the profession will heartily approve. He has appointed a medical advisory board consisting of Drs. Edward G. Janeway, Joseph D. Bryant, T. Mitchell Prudden, William M. Polk, Abraham Jacobi, John W. Brannan, Richard H. Derby, L. Emmett Holt, Alexander A. Smith, Francis P. Kinnient and Henry P. Leonis. These positions are honorary and the members receive no salary. The board selected Prof. Charles E. Chandler, of Columbia University, as consulting sanitarian; Dr. Herman M. Biggs, as medical adviser; Caspar Goldenman, secretary to the board; Dr. J. H. Raymond, assistant sanitary superintendent, in charge of the Department of Health in the Borough of Brooklyn, vice Dr. Robert Black, resigned; H. E. Bramley, chief sanitary inspector, in charge of the first division, vice Dr. M. B. Feeney, resigned; R. C. W. Wadsworth, private secretary to Dr. Lederle, and Dr. Edward F. Hurl, assistant sanitary superintendent for the Borough of the Bronx, taking the place of Dr. Eugene Monaghan, resigned. The Commissioner has announced the reduction of his force by 157. This has been necessitated by the reduction of the appropriation in 1902 to \$667,012. For 1901 the appropriation was \$1,053,290 and \$169,700 additional was expended. The positions of those dropped were not important, and the efficiency of the force will be in no way impaired.

#### Buffalo.

**Marine Hospital in Buffalo.**—Surgeon-General Wyman, of the United States Marine Hospital service, has written to the Secretary of the Treasury setting forth the necessity of a marine hospital in Buffalo.

**Mortality.**—The health report for December shows a death rate of 15.18 per 1000 per annum. Smallpox caused 1 death; pulmonary consumption, 39, and typhoid fever, 10. The total deaths were 446, as compared with 409 in December, 1900. There were 5999 children vaccinated in the public schools.

**Resignation Explained.**—Dr. De Laney Rochester, who recently resigned from the medical staff of the Sisters' Hospital, has issued a signed statement giving the cause of his resignation. He says:

On Monday, January 6, while making my rounds in the contagious ward, I found a case of diphtheria and told the interne to give him 4000 units of antitoxin, and to repeat the dose in twelve hours if there was no improvement. He told me that the hospital would not supply antitoxin to patients unless the patient or someone else paid for it. I told him that I thought he must be mistaken, and asked to see the Sister Superior. I asked her whether the statement of the interne was true, and she replied that the hospital could not supply antitoxin for patients unless the patient or friends or someone outside paid for it. I replied that I could not allow myself to remain connected with an institution which refused what was recognized by all scientific physicians as the only treatment of diphtheria, simply because the patient was too poor to pay for it, and proffered my resignation on the spot, and it was promptly accepted. The point that I make is that no hospital, and especially no charity hospital, has a right to receive patients and not give them the best treatment known to science, regardless of the financial position of the patient."

## PENNSYLVANIA.

### Philadelphia.

**Smallpox.**—Only 82 new cases of smallpox and 16 deaths were reported to the Bureau of Health for the week ended January 18, as against 131 new cases and 15 deaths for the preceding week.

**The Fifteenth German-American Charity Ball** will be given February 3, by the Maennerchor for the benefit of the Southeastern Dispensary and Hospital for Women and Children, and "The Pines," a Country Home for Poor Women and Children. Dr. Fred. A. Packard is president of the honorary board of managers.

**Appointments at Philadelphia Hospital.**—At a meeting of the Department of Charities and Correction, January 13, new appointments of attending physicians at the Philadelphia Hospital were made as follows: Drs. Henry M. Newbold and William Pickett, examiners of the insane, and Dr. Daniel J. McCarthy, neurological registrar.

**Bureau of Charities Report.**—The report of the Bureau of Charities showed that on December 31 there were 4525 inmates of the Philadelphia Hospital and Almshouse, an increase of 381 over the number at the same time the previous year. As a guard against smallpox, Superintendent Geary has ordered a daily medical examination of every inmate and attendant, over 5000 in all.

**Dr. Da Costa's Estate.**—An adjudication was recently filed in the estate of Dr. Jacob M. Da Costa, deceased, making distribution of a balance of \$119,679. Deceased bequeathed \$5000 to the Pennsylvania Hospital and \$2500 to the Children's Hospital for the endowment of free beds. He left to the College of Physicians his medical library and \$5000 for the endowment of the Publication fund; and to the Jefferson Medical College his medical museum.

## GENERAL.

**Leper Settlement of the Philippines.**—The Island of Cagayan belongs to the Jolo group, and is quite isolated, being 60 miles from the nearest land. It is at present inhabited by about 200 Moros, and the work of building a town will be commenced as soon as satisfactory arrangements can be made with the natives. The plans have been perfected for some time. It is estimated that there are about 20,000 lepers in the Philippines, the rounding up of which will be no easy task for the Health Commissioners.

**Dr. Rixey Promoted.**—Captain Pressley M. Rixey, medical director U. S. Navy, formerly attendant physician of President McKinley, has been nominated as Surgeon-General of the Navy, by President Roosevelt, in ratification of the promise of his lamented predecessor. This promotion will give Dr. Rixey the rank of rear admiral. He succeeds Rear-Admiral William K. Van Reypen, who is placed on the retired list to-day, with the rank and retired pay of a senior rear admiral. Dr. Van Reypen has been in the service over forty years.

**Health of Havana.**—Major Gorgas, chief sanitary officer of Havana, has sent to the War Department at Washington a report on the health of Havana, in which he says:

The entire health of the city for the year just ended over the preceding years is something wonderful. There has been a very big decrease in the number of deaths in almost all of the different diseases. This is especially true of yellow fever. There have been few cases in comparison with the record last year, and the last three months of the present year were absolutely free from the disease, which is wonderful, and has not happened in the history of Havana in years of which we have any sanitary statistics. The cause of the decrease in yellow fever is undoubtedly due to the work on the theory that the mosquito is the transmitter of the disease. During the month of December there has been no yellow fever and no smallpox.

**Two Assistant Surgeon-Generals Retire.**—Col. Dallas Bache, recently stationed at Los Angeles, Cal., has retired from the Army after a service of over 40 years. Col. Bache was born in the District of Columbia, entered the service in 1861, and became colonel and assistant surgeon-general in 1895. Col. Charles R. Greeneaf, who has also retired, is a native of Pennsylvania, but entered the service as assistant-surgeon of the 5th Ohio Infantry at the beginning of the war of the rebellion. He reached his present army status in 1896, and has since rendered valuable service in the Philippines. Dr. Greeneaf has been recently stationed at San Francisco.

## CANADA.

**Handsome Donation to Science.**—A prominent and wealthy citizen of Ottawa, Ont., has donated a large sum of money to the Medical Faculty of McGill University for researches in the possible methods of a cure for consumption. The work will be conducted under the supervision of Professor Adami, and Dr. A. G. Nichol has been appointed to prosecute the researches under him.

**Hygiene in Schools.**—Dr. Ruttan, of McGill, recently delivered a lecture to the high school pupils of Montreal on the important question of "School Hygiene," in the course of which he advocated the appointment of physicians to inspect the schools. He instanced the case of Boston, New York, Philadelphia, Washington and Chicago, and strongly advocated a similar system for Montreal.

**Vaccination.**—Dr. Laberge, the Medical Health Officer of Montreal, has reported to the Hygienic Committee that the number of people vaccinated in Montreal since last October reaches to 19,000. A curious sect named "The Saints," near St. Catherine's, are likely to get themselves into trouble with the provincial health authorities. Smallpox has broken out among them and they refuse to be vaccinated. They have all been quarantined, and unless they submit to vaccination they will have the option of going to jail.

**College and Hospital Amalgamation.**—It has been definitely decided by the Governors of the Western Hospital and the Medical Faculty of Bishop's College University, Montreal, that it will be in the interests of both for the amalgamation to take place. For some time the Western Hospital, owing to a largely increased prosperity in the past few years, has been looking about for larger premises, and a new site having been obtained, the construction of a new and more modern hospital will be at once begun. The Medical Faculty of Bishop's will take over the old Western Hospital at the beginning of the session of 1903.

**Indian Vital Statistics.**—According to the recent census the Indian population within treaty limits in Canada numbers 99,527, which is an increase of 517 over 1900. During 1901 there were 2,479 births and 2,240 deaths. In 1900 the births were 2,333, the deaths 2,557. The Indian Commissioner at Winnipeg has recently reported to the Indian Department at Ottawa upon the question of child marriage among certain Indians, chiefly among the Blackfeet, Piegiens and Bloods, and advises that unless the influence of agents and missionaries does not bring about a reform that the Department prohibit child marriage entirely.

**Suit for Alleged Malpractice.**—Burns versus Atherton is a case of considerable interest to the profession in the Maritime Provinces at the present time. Dr. A. B. Atherton, of Fredericton, N. B., is being sued for \$5,000 for the loss of an arm. It appears that the appellant came to the doctor with a dislocation of the shoulder of some five months' duration. Dr. Atherton sought to effect reduction and in the act it is stated ruptured the axillary artery. Amputation of the arm was subsequently performed, and hence the resultant suit. Dr. Atherton was at one time a professor in the Medical Department of Toronto University.

**Appointments.**—Dr. Phillips Weatherbe, of the Canadian Army Medical Service, Wolfville, N. S., has been appointed supernumerary to the Field Hospital Company for South Africa. —Dr. Telesphore Parizeau, lately returned from Continental hospitals, has been appointed professor of pathologic anatomy at Laval University. —Principal Petersen, Dean Roddick, of the Medical Faculty, and Dr. Ruttan have been appointed to represent McGill University at the annual dinner of the New England Society of McGill Graduates to be held at Boston on January 23. —Dr. J. Orlando Orr, Toronto, has been appointed Lecturer on Bacteriology at the Toronto Technical School. —Dr. W. H. Groves (Toronto, '89), has been appointed surgeon to the R. M. S. *Sebondi*, of the African Steamship Company, plying between Liverpool and the West Coast of Africa. —Dr. A. J. G. Maedougall, house surgeon to Toronto General Hospital,

has been appointed medical attache to the regiment in charge of Boer prisoners at Hamilton, Bermuda.

**Personals.** Drs. Leslie and Jennie Dow, Toronto, return to the China Mission Field on January 27. Dr. E. P. Lachapelle is a candidate for mayor at the Montreal municipal elections. Sir James Grant, Ottawa, who has been physician to all of Canada's governors since the time of Lord Monck, lectured in Toronto last week on "How to Live to Prolong Life."—Dr. N. A. Powell, president of the Ontario Medical Association, entertained Dr. W. H. Drummond, of Montreal, during his recent visit to Toronto. A large number of medical men were invited to meet Dr. Drummond, and the profession spent a very pleasant social evening. Dr. O. Bjornson, Winnipeg, and Dr. B. J. Bjornson, North Dakota, have gone to Europe for a year's hospital work. Both gentlemen are graduates of the Manitoba Medical College, and served as house surgeons in the Winnipeg General Hospital for a year after graduation. Dr. H. L. Dickey, Charlottetown, P. E. I., has moved to Halifax, N. S., to practice eye, ear, nose and throat.

#### FOREIGN.

**Plague.** Deaths from the bubonic plague in India amount to about 1000 per day; in Bombay between 140 and 200 die of the disease daily, and in Calcutta only about 25.

**Deaths Abroad.** The death of the prominent physician and former professor of pathologic anatomy, Dr. Axel Key, is reported from Stockholm. He was the founder of the *Nordiskt Med. Arkiv* and its editor for thirty-two years. — Dr. Destrière, professor of therapeutics at Brussels, has died recently, in his 43d year. The medical faculty of Alger, in Algeria, lost almost simultaneously last month three of its professors: Professor Blaise died suddenly while delivering a lecture, and Professors Gemy and Bourlier succumbed to chronic affections.

#### PARIS LETTER.

##### The New Law on Hygienic Beverages.

The new law suppressing taxes on so-called hygienic beverages, such as wine, cider, beer, is not bringing about the wished for result. It was thought that the increased taxes on liquors would compensate for the deficiency resulting from this law, and that moreover a smaller amount of the latter would be drunk. So far, however, from this being the case, there is a considerable deficit in the budget caused by the application of this law, and the hygienists can not consider that the public health will be much benefited. More wine is drunk, there being an increase of 6,000,000 of hectoliters, but on the other hand it is doubtful whether less alcohol is absorbed. Liquorsellers had laid in large stocks of spirits so as to escape the new tax, and the fact that less alcohol has been taxed is no proof that a smaller quantity has been drunk. For the last five or six years the vintage of France has increased noticeably, phylloxera having been stamped out to a great extent by the planting of American shoots. There is at present over production, 65,000,000 of hectoliters being produced in 1900, and 55,000,000 in 1901. The yearly consumption is only 42,000,000, which would seem to be the amount that can be drunk from a hygienic point of view, so that a good deal is left on the market. There are parts of France where wine is sold at a cent a bottle. A remedy for this would be the distillation of the inferior qualities of wine, the alcohol produced being used in the preparation of liquors, instead of the manufactured alcohol so largely employed nowadays.

##### Chantemesse's New Antitoxin for Typhoid Fever.

At the Congress of Madrid held in 1898, Dr. Chantemesse had read a report on a special antitoxin he had prepared against typhoid fever. He has been doing some more work on the same subject recently and chose this as the title of his first lesson at the School of Medicine in his course of experimental and compared pathology. He has been trying this serum on a hundred patients suffering from typhoid fever, and his statistics seem to be quite favorable to this mode of treatment. Dr. Chantemesse treated 29 patients at the Baston, and they all recovered. At the Tenon Hospital out of 44 cases treated by the usual methods, there were 14 deaths, whereas 30 other cases chosen among the most serious ones furnished 4 deaths only. Dr. Chantemesse considers that the mortality in typhoid fever is much greater than is generally supposed, it being as high as 29 per cent. With this new treatment there were only six deaths out of a hundred cases, 3 from intestinal perforation, one from pneumonia, another was injected only on the 25th day, and another had a large sacral eschar. The amount injected is about 10 to 12 cubic centimeters, and the injection is made in the arm. The result is to produce in two

or three days a rapid decline of the temperature, and an increase in the quantity of urine excreted. If the injection is made before the tenth day, the result is much more rapid. The temperature goes up in some cases towards the 20th day and a new injection is found necessary, 4 to 5 cubic centimeters being sufficient. Dr. Chantemesse considers that this method of treatment should be used even when the presence of typhoid fever is not a certainty. [See THE JOURNAL, Dec. 14, p. 1640.]

##### The Typhoid Fever Scare at Cannes.

Last April quite a number of cases of fever were treated at Cannes, and there was a report that they were due to an epidemic of typhoid fever. Dr. Roustan, a physician of the town of Cannes, has written an article to the *Presse Medicale*, in which he endeavors to show that most of the cases seen were abdominal forms of grippé, presenting as characteristics the sudden attack, and the relatively short duration of the disease. Dr. Roustan's attempt to whitewash the medical statistics of Cannes is certainly very praiseworthy. It should be remembered that gastrointestinal forms of grippé are surely followed by death, as proved to be the case a certain number of times at Cannes.

##### Celebration of the Internes and Externes.

Every year when the examinations for the nomination of internes take place, a ball is given by the internes to the externes. This year several of the hospitals composed processions indicative of modern topics. One was the Triumph of Cocain, a procession made up by the internes of the Hôtel Dieu, the manner in which cocain is gathered, and its use either locally or by lumbar puncture is figured by different groups. It seems rather strange that it should be the hospital which lost two patients from spinal cocainization that chose this subject.

## State Boards of Registration.

**Missouri State Board of Health.**—The State Board of Health met at Jefferson City, January 7, and re-elected Dr. A. W. McMaster (R.), Columbia, president; Dr. Benjamin G. Dysart (R.), Paris, vice president, and Dr. Winn F. Morrow (R.), Kansas City, secretary.

**State Board of Health of Illinois.**—At the annual meeting of the State Board of Health, held at Springfield, January 14, Dr. George W. Webster (R.), Chicago, was elected president; Dr. James C. Sullivan (R.), Cairo, treasurer, and Dr. J. A. Egan (R.), Chicago, secretary.

**Wisconsin Medical Board Election.**—At the annual meeting of the State Board of Medical Examiners, held in Milwaukee, January 14, Dr. John R. Currens (R.), Two Rivers, was elected president, and Dr. Filip A. Forsbeck (H.), Milwaukee, secretary. The two new members, Dr. J. V. Stevens (elective), Jefferson, and Albert N. Jouris (osteopath), La Crosse, met for the first time with the Board.

**Officers of Indiana Board.**—The State Board of Medical Registration and Examination held its first regular session of 1902, January 14, at the State House and elected the following officers for the year: President, Dr. W. A. Spurgeon (P.M.), Muncie; vice president, J. C. Webster (R.), Lafayette; secretary, W. F. Currier (E.), Indianapolis; treasurer, Dr. J. M. Dinnen (R.), Ft. Wayne.

**Registration in Kansas.**—The secretary of the Kansas State Board reports that up to January 8, 2587 physicians had registered. Only 6 had refused to comply with the law. The penalty for violation is a fine of from \$50 to \$200. Of illegal practitioners 127 have been barred from practice, about 12 of whom have made application for reinstatement. Forged or worthless diplomas caused the exclusion of 25.

**Ohio State Board Elects Officers.**—The Ohio State Board of Medical Registration and Examination met in Columbus, January 7, and re-elected the following officers: President, Dr. N. R. Coleman (R.), Columbus; vice president, Dr. H. E. Beebe (H.), Sidney; treasurer, Dr. David Williams (E.), Columbus; secretary, Dr. Frank Winders (R.), Columbus. The Board disposed of the case of G. A. Purpura, an Italian of Cleveland, charged with practicing medicine under another man's certificate, by revoking the certificate.

**State Board of Health of Rhode Island.**—The following is the result of the examination for state license, held at Providence, January 2; percentage required to pass, 75; number of questions, 70; number of candidates, 9; passed 4, rejected 5:

| PASSED.          |                   |                                     |               |               |
|------------------|-------------------|-------------------------------------|---------------|---------------|
| Candi-<br>dates. | Sch. of<br>Pract. | College.                            | Year<br>Grad. | Per-<br>cent. |
| 145              | R.                | Tufts College Medical School.....   | 1901          | 82.6          |

**Reciprocal Federation of State Examining Boards.**—A meeting of members of reciprocating boards was held in Chicago, Jan. 17, 1902. There were present: Drs. Curryer (sec.), Spurgeon (pres.) and Dinnen of Indiana; Drs. Currens (pres.) and Ludwig (sec.) of Wisconsin; Dr. Egan (sec.) of Illinois; and Dr. Harison (sec.) of Michigan. Dr. J. R. Currens was elected president; Dr. Dinnen, vice-president; Dr. Spurgeon, treasurer, and Dr. Harison, secretary. The following name was adopted: "The Confederation of Members of Reciprocating State Medical Examining and Licensing Boards." A committee appointed to draft a policy in matter of uniformity and reciprocity of state licenses reported as follows: 1. That a license or certificate of qualifications of at least one year's standing, based upon presentation of a satisfactory diploma and an examination before a board in specified branches of medicine and surgery, may be accepted at the discretion of a board in lieu of an examination as a basis upon which the state license may be issued. 2. That a license or certificate of qualification issued by a state board of medical examiners, of at least one year's date, based upon presentation of a satisfactory diploma and upon the recommendation of the board of medical examiners as to the reputability of the applicant, may be accepted at the discretion of the board in lieu of an examination as a basis upon which the state license may be issued. The report was adopted. States entering into reciprocity will be guided by the above, but will itemize a standard of preliminary qualification and medical course covering 48 months in a reputable college. The meeting adjourned to May next, when constitution and by-laws will be passed.

**Rhode Island.**—Since our publication on Nov. 16, the medical practice act in Rhode Island has been amended, making examination necessary before receiving a certificate.

Section 1 of the new law requires the town or city clerk to keep a register of physicians and to periodically make report from same to the State Board of Health.

Section 2 makes the practice of medicine unlawful without the registration of a certificate or authority to practice. Persons registering must subscribe and verify by oath to the said clerk his authority for practicing medicine as prescribed, together with age, address, place of birth, and school or system of medicine to which he or she proposes to belong.

Section 3 prescribes that the authority to practice medicine shall be a certificate from the State Board of Health, which board shall, upon application, after examination, issue a certificate to any reputable physician who intends to practice medicine or surgery in the State, and he shall present himself before the State Board of Health and pass satisfactorily such examination as the State Board may require. The fee for examination is \$10, and not over \$2 for certificate.

Section 4. "Nothing in this chapter shall be so construed as to authorize any itinerant doctor to register or to practice medicine in any part of this State."

Section 5 provides for the refusal by the board to grant certificates to persons not of good moral character, or who have violated the laws of the State, or been guilty of gross unprofessional conduct or conduct of a character likely to defraud the public; also to revoke any certificate granted by it after due notice or hearing for like cause or any fraud or deception committed in obtaining such certificate or any other cause which shall in the opinion of the board render the holder of such certificate an unfit person to practice medicine in the State. It also provides for legal proceedings, for administering oaths and the summoning of witnesses, and that any person swearing falsely shall be guilty of the crime of perjury. It provides also for appeals to the Appellate Division of the Supreme Court.

Section 6. "Nothing in this law shall be so construed as to discriminate against any particular school or system of medicine or prohibit gratuitous services in cases of emergency, nor does this chapter apply to commissioned surgeons of the U. S. Army, Navy, or Marine-Hospital Service, or to legally authorized physicians of another State, called to see a particular case, in consultation with a registered physician of this State, who do not open an office or appoint any place in this State where they may meet patients or receive calls.

Section 7. "Complaints for violation of the provisions of this chapter shall be made by the Secretary of the State Board, and such secretary shall be exempt from giving surety for costs on any complaint made as aforesaid.

Section 8. "Any person who, not being lawfully authorized to practice medicine within this State, and so registered according to law, shall practice medicine or surgery or attempt to practice medicine or surgery, or any of the branches of medicine or surgery, after having received therefor or with the intent of receiving therefor, either directly or indirectly, any bonus, gift, or compensation, or who shall open an office with intent to practice medicine or shall hold himself out to the public as a practitioner of medicine, whether by appending to his name the title of doctor or any abbreviation thereof, or M.D., or any other title or designation implying a practitioner of medicine, or in any other way, shall be deemed guilty of a misdemeanor, and upon conviction thereof shall be fined \$50, and upon each and every subsequent conviction shall be fined \$100 and imprisoned thirty days, either or both, in the discretion of the court; and in no case when any provision of this chapter has been violated shall the person so violating such provision be entitled to receive compensation for services rendered."

The law does not provide for the times of meeting of the Board, but they are held quarterly, in January, April, July and October, as in the previously published law.

The Secretary of the State Board of Health is Dr. Gardner T. Swarts, Providence.

## Correspondence.

### Unjust Rejection of Applicants to Medical Societies.

PARIS, ILL., Jan. 14, 1902.

*To the Editor:*—When a young man has been turned down by some clique or someone who is jealous of him, he naturally feels that he has been unfairly treated, and is an enemy of medical societies as long as he lives. I believe in giving the young man a chance to show that he is a gentleman; then if he shows himself unworthy it is easier to deal with him as a member of a medical society than as an outsider. I believe that many a young physician who would have proved himself a faithful and honorable member of the profession, has become a quack because he has been deprived of the good influences of a medical society. My experience as a member of a board of censors has shown how quite a number of bright young men are kept out of our medical societies.

It is a significant fact that where there is a specialist on the board, an applicant who practices his specialty is quite likely to have been guilty of some irregularity and is therefore ineligible.

If the case is brought before the society, a few whose reputations are a little shady—like the pickpocket who cries stop thief—make frantic appeals for the honor and good name of the society, and vote against the applicant, while a large majority of the members present do not vote. Respectfully,

W. H. TEN BROECK, M.D.

## Book Notices.

**CLINICAL HEMATOLOGY.** A Practical Guide to the Examination of the Blood, with Reference to Diagnosis. By John C. Dalton, Jr., M.D., Assistant Demonstrator of Clinical Medicine, Jefferson Medical College, Hematologist to the German Hospital, etc. Containing 8 Full-page Colored Plates, 3 Charts, and 48 Other Illustrations. Philadelphia: P. Blakiston's Son & Co., 1901.

Hematology has grown with remarkable rapidity during recent years. The present work is in every respect a worthy companion of its predecessors in the same field in this country, namely, the books by Cabot and by Ewing. The purpose is to furnish a practical guide to blood examination by methods adapted to routine clinical work and to furnish the data necessary to interpret the findings according to their true values as clinical signs. The style is clear and pleasing. The colored illustrations made by Mr. E. F. Faber show artistic skill and faithful reproductions of structural details. The information furnished seems to be all that any one may expect in a book.

Nearly 500 pages and it is arranged in a very practical and satisfactory manner. The references to the literature are given at the bottom of the pages, and they are arranged in uniform manner, the year, volume, and page being given in the order mentioned. In addition to the usual index there is an index of authors filling nearly six pages.

The author has succeeded in including facts of the most recent acquirement, and literature from 1901 is freely quoted. The specific precipitation test for human blood is described (pages 88 and 89). In this section and again in the index the name Uhlenthal is misspelled Uhlennuth. The agglutination test of blood serum is referred to as Widal's test (page 86). On account of the cloud which rests upon Widal's right to be thus distinguished (see statement of circumstances by Durham, *Jour. of Exp. Med.*, 1901, v., 351) many would no doubt prefer to have Widal's name given less prominence in connection with some of these reactions.

The original data given in the book represent something like 1000 examinations of the blood in various pathologic conditions. The author has improved his opportunities well, and he is entitled to the hearty congratulations of his colleagues for the thoroughly satisfactory and comprehensive manner in which he has fulfilled the task before him.

**ANATOMY IN ITS RELATION TO ART.** An Exposition of the Bones and Muscles of the Human Body with Especial Reference to Their Influence Upon Its Actions and External Form. By George McClellan, M.D., Professor of Anatomy of the Pennsylvania Academy of Fine Arts. Illustrated by 338 Original Drawings and Photographs Made by the Author and Expressly Prepared for This Work. Cloth. Pp. 433. Price, \$10.00. Philadelphia and London: W. B. Saunders & Co., 1901.

This work has been prepared for art students. The artist's aim is to know the human form so that he may reproduce that form on canvas or in marble. The physician and those who are interested in physical training, or in anthropology, will also find in this book a wealth of suggestions for physical development. The illustrations consist of photographs of the nude male and female forms in various poses, side by side with photographs of some of the masterpieces of sculpture in like poses. Photographs of the skeletons by the side of the living nude form in the same positions make startling parallels. The book certainly will be a welcome one to the artist whose ideals are those which come nearest to nature. The descriptive text is in simple language, accurate, and in detail sufficient to describe the illustrations. The book is a magnificent production and a credit alike to Prof. McClellan and to the publisher, and a fair sample of American enterprise in a new field.

**REGIONAL ANATOMY OF THE HEAD AND NECK.** A Text-Book for Students and Practitioners of Dentistry. By William T. Eckley, M.D., Professor of Anatomy in the Chicago College of Physicians and Surgeons, etc., and Corinne B. Eckley, M.D., Professor of Anatomy, Chicago School of Anatomy and Physiology, etc. In One Octavo Volume of 240 Pages, with 36 Engravings and 20 Full-page Colored Plates. Cloth. Price, \$2.50 net. Philadelphia and New York: Lea Brothers & Co.

The authors of this work have successfully endeavored to make plain the intricate anatomy of the head and neck. The puzzling phenomena of reflex pain in sound teeth due to remote lesions, is fully considered from the standpoint of the dentist; a chapter is devoted to the boundaries and triangles of the neck. Though written primarily for the dental student and

practitioner it will be found a convenient book of reference for the physician. The plate illustrations are excellent and numerous. The mechanical workmanship of the volume is in every respect a credit to the publishers.

**WATER AND WATER SUPPLIES.** By John C. Thresh, D.Sc. (London), M.D. (Victoria), D.P.H. (Cambridge). Third Edition, Revised and Enlarged. Cloth. Pp. 527. Price, \$2.00 net. Philadelphia: P. Blakiston's Son & Co., 1901.

This is the third edition of a standard work which, though small in size, covers its subject to such an extent that it is perhaps as often quoted as any. The author's remarks are throughout judicious and his ideas as to the importance of the study of the source of water supply as well as the using of chemical and bacteriologic examinations are such as ought to be pretty thoroughly impressed upon those who have to do with this subject. The legal portion of the work has been revised and may be presumed to be thoroughly up to the most recent English laws. He has also added a chapter on the protection of water supplies. The book is one that will maintain its position as one of the leading works on its subject.

**PHOTOTHERAPY.** By Professor Niels R. Finsen, Copenhagen, Translated from the German Edition, with an Appendix on the Light Treatment of Lupus by James H. Sequeira, M.D., Lond., M.R.C.P., Dermatological Assistant, etc. London: Edward Arnold, 1901.

This is a small book of 79 pages containing Finsen's papers on, 1, the chemical rays of light and smallpox; 2, light as a stimulant; 3, the treatment of lupus vulgaris by concentrated chemical rays. An editorial abstract of the French issue appeared in *The Journal*, Sept. 15, 1900. The profession in general are probably well acquainted with the favorable opinion of those best qualified to judge of Finsen's light treatment of lupus. The appendix by the translator gives the results obtained up to the present time. The book is interesting reading and may be said to be the cornerstone of phototherapy.

## Married.

FRANK H. RUSSELL, M.D., to Miss Clara Platt, both of El-dred, Ill., January 1.

JOHN H. SUGEL, M.D., to Miss Estella C. Peers, both of Collinsville, Ill., January 8.

AMOS F. MOORE, M.D., Dixon, Ill., to Miss Frances C. Smith, of Cheboygan, Mich., January 21.

ROBERT A. McLENN, M.D., San Francisco, Cal., to Mrs. Viola Given, of Los Angeles, Cal., January 6.

EUGENE MARTIN, M.D., Chicago, to Mrs. Hertha von Cotz-hausen, of Milwaukee, Wis., January 11.

WILLIAM G. RICE, M.D., Muncie, Ind., to Miss Minnie R. Sutherland, of Cheboygan, Mich., January 1.

FRED JOHNSON, M.D., Lake Nibaugon, Wis., to Mrs. Mary E. Walters, Oregon, Wis., at Beloit, Wis., January 1.

CHARLES CLARENCE BILLINGSLEY, M.D., U. S. Army, to Miss Lucy Mabel Graham, of Westminster, Md., January 9.

LAWRENCE ALEXANDER CLEVERDON, M.D., Stillwater, Okla., to Sara Honora Hogarty, M.D., at Quindaro, Kan., January 15.

## Deaths and Obituaries.

### Dr. James Rodman.

"Dr. James Rodman died at his home in Hopkinsville, Ky., a few days ago." This announcement brought grief into many a household. Wherever known he was admired and loved. The poor whom he had so often befriended, the rich who so often had assisted him to make the burden of life smoother for the poor, the children who were always his special pets, and the insane (would that they could speak!) heap blessings upon his head and place a laurel wreath of love on his cold brow. A great man has fallen, and the medical profession of Kentucky bemoans his death. As a citizen he was of the highest type; as a man, "a prince among men"; as a companion, he was the most charming, and no man ever knew a truer or more devoted friend.

In appearance Dr. Rodman was of that type that, by his very presence, commanded respect and admiration. He was tall, erect, slim of stature, always neatly attired, with a face

pleasant to look upon. His eyes laughed his thoughts, and conveyed always a truthful sincerity; his mouth showed firmness in expression, yet lighted often with a smile and betokened an unflinching integrity mellowed with much kindness. A voice always pleasing, and a rapid articulation indicated the quick thought of a well-trained mind. At repartee he was *facile princeps*. Quick, alert, with a quiet sarcasm he could always silence his adversary, yet command his respect. As a writer of pure English he scarcely had a superior—clear, convincing, and always logical. As an alienist he had but few equals; his writings in this line of thought made him an international reputation. His family was one of physicians. His brother Hugh was a leading practitioner in our capitol city, and a nephew, Dr. Wm. B., was a physician and surgeon of promise until stricken down by disease. Another nephew, who was very dear to him, is Dr. William L. Rodman, the distinguished professor of surgery in the Medico-Chirurgical College in Philadelphia and the Woman's Medical College of Pennsylvania.

Dr. Rodman was born in New Castle, Ky., in 1829, and graduated from the Medical Department of the University of Louisville, in 1849. In 1863 he was appointed superintendent

DR. JAMES RODMAN.

of the Hopkinsville Asylum for the Insane, and in 1889 resigned the position, after holding the office for 26 consecutive years. He could have remained during his lifetime, and was besought to do so, but being a man of wealth he preferred the comforts and solace of his home after this long service. The asylum during his administration was a model institution. It was often visited by the leading alienists of the country and of Europe. He was regarded by many as the best asylum superintendent in America, and his work certainly evidences the fact. He was also the first superintendent of the Feeble-Minded Institute at Frankfort, and to his clear head and able management this unfortunate class received much benefit. "Take him all in all we shall not see his like again." The state has lost a valued citizen, the medical profession an honored member, and the writer a most dearly beloved friend. Peace to his ashes!

JOSEPH M. MATHEWS.

#### Drs. Clayton Parkhill and John T. Eskridge.

Two eminent physicians of Denver died on January 16, and the cause of death in each case is said to have been Bright's disease. Dr. Clayton Parkhill and Dr. J. T. Eskridge were not only closely associated, but were leading men in their respective specialties of surgery and neurology. Curiously enough Dr. Parkhill's death was directly due to appendiceal abscess, a surgical affection in which he was especially interested, while

Dr. Eskridge's was from cerebral hemorrhage, a condition which came within the limits of his own specialty.

Clayton Parkhill was born at Vanderbilt, Pa., in 1860. He was graduated from the Jefferson Medical College in 1883, and from the Pennsylvania School of Anatomy and Surgery in the same year. After a year's service on the resident staff of the Philadelphia Hospital he became demonstrator in the Pennsylvania School of Anatomy and Surgery. He then engaged in active practice for a short time, but was obliged to abandon his practice in the East on account of his failing health and moved to Denver in 1885. He speedily built up a valuable practice, and two years later was one of the founders of the Gross Medical School, in which he held the chair of clinical surgery at the time of his death. He was appointed surgeon-general of the state. At the outbreak of the Spanish-American war Dr. Parkhill was appointed major and surgeon. He was first ordered to the Philippines, and while in California awaiting transportation was transferred to Porto Rico, where he remained for a year as chief surgeon of the 7th Army Corps. While in service he contracted malaria, and this was followed by disease of the kidneys. A week before his death he was attending to practice although in a weakened condition. At the

DR. CLAYTON PARKHILL.

autopsy the fact was revealed that the primary cause of death was abscess around the appendix. Dr. Parkhill had an enviable reputation as surgeon and as a contributor to medical literature. He was a member of the American Medical Association, the Association of Military Surgeons of the United States, American Surgical Association, Rocky Mountain Interstate Medical Association, Association of American Anatomists, member and ex-president of the Colorado State Board of Medical Examiners, a member of the Colorado State Medical Society and the Denver Clinical and Pathological Society. He was also surgeon at St. Luke's and the Arapahoe County hospitals.

Dr. John T. Eskridge, one of the foremost neurologists of the country, died at St. Luke's Hospital, Denver, January 16. The direct cause of death was cerebral hemorrhage, but he had been afflicted for a long time with disease of the kidneys. Dr. Eskridge was recognized as one of the leading neurologists of the country, and his contributions to the literature of this subject have been many and valuable. He was born in Delaware in 1847 and was graduated from the Jefferson Medical College in 1875. He was immediately made post-graduate instructor of nervous disease in his alma mater and then practiced in Philadelphia until 1884 when, on account of his health, he moved to Colorado Springs where he speedily secured an extensive practice. After a stay of two years at Colorado Springs,

during which time the intermediate hemorrhage of the lungs from which he suffered had completely ceased, he went to Denver where he practiced until his death. He was a voluminous writer and was the author of about 170 pamphlets and treatises on neurology and kindred subjects. He was a member of the American Medical Association, of the American and the Philadelphia Neurological associations, of the American Medical Psychologic Association, of the New York Medical Legal Association, of the Apache County and Denver Medical societies and presi-

DR. JOHN T. FISKRIDGE.

dent of the Colorado State Medical Society. He served as president of the Board of Trustees of the State Insane Hospital for one term, was alienist and neurologist at the Apache County Hospital, neurologist at St. Luke's Hospital, and had been at the head of the department of nervous and mental diseases at the University of Denver and the University of Colorado.

**William C. David, M.D.** Queen's University and Royal College of Physicians and Surgeons, Kingston, Ont., 1889, an esteemed practitioner of West Superior, Wis., died at his residence in that city from tuberculosis, January 9, after a lingering illness, aged 40. His funeral was under the charge of the Douglas County Medical Association, of which he was a member.

**John H. Spurrier, M.D.** Medical College of Indiana, Indianapolis, 1879, one of the oldest physicians of Rush County, Ind., died at his home in Rushville, after a protracted illness, January 9, aged 73. He served in the Civil war as assistant surgeon in the 16th Indiana Volunteers and later as surgeon of the 123d Indiana Volunteers. He was also local health officer for several years.

**James M. Sweeney, M.D.** Niagara University, Buffalo, N. Y., 1892, a popular physician of Utica, N. Y., died at his home in that city, January 10, from apoplexy, aged 55. He served during the Spanish American war with the 3d U. S. Infantry and was present at the battle of San Juan Hill and was afterward on duty at the yellow fever hospital at Santiago.

**Robert Leeper Sweeney, M.D.** Western Reserve University, Cleveland, Ohio, 1819, one of the oldest practitioners of Ohio, died at his home in Marion, January 12, aged 80. He was one of the founders, and for many years the president of the Marion County Medical Society, and served as surgeon of the 43d Ohio Volunteers during the Civil war.

**Alfred Neale Mahon, M.D.** Jefferson Medical College, Philadelphia, 1897, son of Dr. John B. Mahon, Pittston, Pa., died at his home in that city, January 12, from nervous pro-

stration following typhoid fever contracted while in the United States service as surgeon on the transport *McClellan*, aged 25.

**Robert A. Brunson, M.D.** Louisville Medical College, 1841, a pioneer practitioner of Los Angeles County, Cal., and a son of Dr. Robert Brunson (Surgeon General under General Jackson in the War of 1812), died January 7 at his home in Norwalk, Cal., aged 80.

**Joseph W. B. Kameier, M.D.** Jefferson Medical College, Philadelphia, 1871, one of the best known physicians of Westmoreland County, Pa., died at his home in Greensburg, after three years of invalidism from paralysis, January 13, aged 56.

**William Hausman, M.D.** Northwestern University Medical School, Chicago, 1874, died at his residence in Kewaskum, Wis., January 14, aged 48. He was a member of the Brainerd Medical Society and its secretary since 1879.

**Nicholas Timary, M.D.** University of Vienna, Austria, 1875, while despondent over the death of his wife, his own impaired health and financial worry, shot himself through the heart, in his office in Cincinnati, January 14, aged 52.

**Ambrose M. Kinnamon, M.D.** Starling Medical College, Columbus, Ohio, 1873, who had practiced in Fairbury, Neb., for quarter of a century, died at his home in that city, January 9, after a lingering illness, aged 58.

**Louis D. Masson, M.D.** Albany (N. Y.) Medical College, 1900, house physician at the Cohoes (N. Y.) hospital, died at that institution, January 10, after an illness of five days, from appendicitis, aged 28.

**John N. Weston, M.D.** College of Physicians and Surgeons, New York City, 1888, is reported to have died in De Lamar, Idaho, December 30. He was formerly a practitioner of Santa Cruz, Cal.

**George H. Thuman, M.D.** Cincinnati College of Medicine and Surgery, 1881, died suddenly while making a professional call in Cincinnati, from heart disease, January 14, aged 45.

**Alexander J. Sanderson, M.D.** University of Pennsylvania, Philadelphia, 1853, an old and prominent physician of Vaiden, Miss., died at his home in that place, January 6, aged 78.

**William P. Wilcox, M.D.** College of Physicians and Surgeons, New York, 1883, formerly of Omaha, died at the Grand Pacific Hotel, Nebraska City, Neb., January 14, aged 39.

**Terrence Sparham, M.D.** McGill University, Montreal, 1841, one of the oldest practitioners of Brockville, Ont., died at his home in that place, January 11, aged 89.

**Anson S. Thompson, M.D.** Cincinnati, 1856, who had practiced medicine in Ellisburg, N. Y., for more than forty years, died suddenly at his home in that place, January 8.

**A. John Law, M.D.** Queen's College, London, Eng., 1872, a well-known physician of Long Pine, Neb., died in a hospital in Omaha, January 7.

**Stephen H. McManigle, M.D.** Western Reserve University, Cleveland, Ohio, 1873, died suddenly at his home in Harper, Kan., January 12.

**Thomas H. Bernard, M.D.** University of Nashville, Tenn., 1857, died at his home in Spring Garden, Ill., January 6.

## Miscellany.

**A Remedy for the Commission Evil.**—The division of fees between the consultant and family physician and the auctioneering of his case by the general physician among rival surgeons and specialists, is an evil that flourishes to such a degree that it can no longer be ignored. If not stopped it will surely undermine all professional ethics and *esprit de corps* and bring us as a whole to irremediable disgrace. The remedy plainly lies in the hands of the medical societies. Let them expel a member who is convicted. When the shameless transaction exists it can not be long hidden and evidence of guilt can easily be secured. The House of Delegates of the American Medical Association at its next meeting should come to some determination upon this subject and should set the example for all smaller and less powerful organizations. A decisive command upon the part of our National Society would constitute the beginning of the end of this professional scandal.—*American Med.*

**Berthelot's Jubilee.**—A souvenir plaque struck off at the mint was presented to the French chemist, Berthelot, on the occasion of the 50th anniversary of his professional career, November 24. The address on behalf of the Académie de Médecine at the ceremonies, stated that he had "enlarged the limits of biology," and in his studies of the mechanism of animal heat had thrown new light on many chemical and vital problems.

**Medical Reports from China.**—The Imperial Maritime Customs department in China publishes a semi-annual series of medical reports from English physicians at the various ports. Dr. Hall writes from Chungking that tuberculosis in its varied form affects more than half of all the people. The glandular form is most severe and so rapid in its progress that operation yields discouraging results. Pulmonary tuberculosis, on the other hand, yields readily to treatment. Dr. Park observes in his letter from Soochow: "In this land of opium smoking, we are often called upon to treat impacted feces. Injection of hydrogen dioxid accomplishes the desired result."

**Gonorrheal Strictures in Female Urethra.**—Imbert contributes an article on this subject to the December *Annales des. Mal. des Org. Gen.-Urin.* It is based on 25 cases of stricture which he has collected and from which he deduces that it is impossible for gonorrheal strictures, like those in men, to develop in the female urethra. There is not a single observation on record in which the gonorrheal nature of the stricture is conclusively proven, he states. Before assuming the gonorrheal character of a stricture of the female urethra the possibility of other affections that may induce stenosis must be borne in mind, also of a congenital stricture, spasm, polypus, cicatrices, results of difficult child-birth or senile stricture.

**Etiology and Treatment of Chorea.**—Heubner states that in 27 cases of rheumatism that came under his observation, 2 of the patients had had chorea previously, and 32 per cent. of 77 cases of chorea had acquired the chorea with or after rheumatism. He attributes genuine chorea to a rheumatic, i. e., an infectious origin. Among the arguments in favor of this view are the prevalence of chorea in rheumatic families, the rheumatic exanthemata observed in some cases of chorea, the tendency of both diseases to a protracted course and to recurrence. Both are frequently complicated by endocarditis, irrespective of the severity of the primary affection. Chorea may also follow gonorrhœa, suppurative angina, scarlet fever or measles, which in these cases are the equivalents of rheumatism. The motions in genuine chorea resemble those induced by emotions, and consequently, genuine chorea is never observed in children too young to have learned to express their sentiments by appropriate muscular movements. This assumption of the infectious-toxic etiology of chorea indicates the importance of rest in bed and of diaphoresis in the treatment, supplemented by arsenic.

**Investigation of Blood, Urine, etc., by Refraction.**—A. Strubell has improved his method of analyzing the organic fluids, etc., by their refracting properties, and announces that the results of the test are so constant that it affords new criteria for physiologic and pathologic problems. The technique is extremely simple and easy. It is effective even with a single drop of the fluid, and he considers it the most reliable as well as the most convenient of all current means of physico-chemical research. The simple instrument used for the purpose is a small hand telescope, magnifying ten diameters, with a prism in the lower end, which is immersed slanting in the fluid into which the light is reflected from a mirror. When a single drop is to be examined, it is placed on the refracting surface of a second small prism on the principle of Abbé's refractometer. He publishes in the *Deutsches Archiv f. Klin. Med.* (Leipsie), lxi, p. 521, comparative tables showing the freezing-point, density and refraction index of the urine in nearly fifty subjects and of a large number of other fluids. He finds that the refracting property is a specific quality that does not vary so widely as the freezing-point and the density. The latter can be computed when the proportions and refractive index are known or vice versa.

**The Problem of Fecundation.**—Boveri delivered an address on this subject at the German Naturforscher Congress in October. He explains fecundation as the supplying to the ovum of the centrosome which starts the segmentation of the cells. Two cells from different individuals coalesce to form a new being. The ovum has everything required for the new being except the impulse to start its growth. It is like a watch perfect except for the missing mainspring. The spermatozoon supplies this impulse. It is the centrosome without which segmentation is impossible. The sexual difference between the ovum and the sperm cell is not fundamental. It merely represents a division of tasks. The ovum can not develop without the missing centrosome—the sperm cell—and the centrosome can not develop without the protoplasm and food material which are contained in the ovum. It is impossible for two organisms composed of numerous cells to coalesce in this way. The process can occur only with two single cells. The pairing of two cells is not the indispensable prerequisite for development. The prerequisite is the possibility of this pairing by a single cell. The ovum probably possessed the property of independent development in primitive forms of animal life, but in the course of evolution it has divided up the task, and now development is only possible when the sperm cell entrusted with a certain part of the task can cooperate with it.
